Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

+ *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
+ *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
+ *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.
+ *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.

Über Google Buchsuche

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter `http://books.google.com` durchsuchen.

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

CASES IN PRACTICE.

Reported by JOHN W. MARTIN, M.D., M.Ch. Q.U.I.

Assistant Medical Officer to the Mayfield Factory Dispensary, Portlaw, late Assistant Surgeon to the North Tipperary Light Infantry Militia.

Valvular Disease of the Heart.

CASE II.—Timothy Reardon, æt. 45, labourer. (Notes taken July 31st, 1871.)

Symptoms.—Complains of being "caught" in the chest at a point midsternum, opposite the articulation of the second rib, the slightest exertion producing dyspnœa. For some time past has noticed a growing inclination to sleep during the day. Has never been troubled with palpitations, headache, or vertigo. Feels better after meals than when the stomach is empty.

Physical Examination.—No enlargement of the area of cardiac dulness, or of the area of impulse. Cardiac action strong and regular. A loud, well-marked murmur resembling the sound made by a carpenter when sawing wood, is heard in its maximum intensity, at the articulation of the second rib right side, this murmur is propagated in the direction of the long axis of the heart, towards the apex. It is synchronous with the closure of the semilunar aortic valves, replacing the second sound, and alternating with the heart's impulse.

A similar but more marked "bruit" synchronous with the heart's impulse and radial pulse, is heard, below the sterno-clavicular articulation, on the left side, the direction of its propagation being in the course of the arch of the aorta, and great vessels of the neck. It is not to be detected over the aortic valves.

At the ensiform cartilage to the left side, a well-marked murmur of a smoother character, is heard preceding the radial pulse and cardiac impulse, resembling closely the noise made by a carpenter's plane passing over a smooth piece of deal board whilst taking off pretty deep shavings. Respiratory system normal.

History.—Previous to the month of June, 1869, always considered himself to be a healthy man. In that month, he had a bad attack of rheumatic fever, in the course of which presystolic mitral, and systolic aortic murmurs developed themselves. The present attack commenced about three months previous to the date of these notes (July 31st, 1871), with a sense of oppression about the chest, anorexia, frequent fits of vomiting, severe lumbar pain, followed by spasmodic attacks of pain in the left hypochondriac region; this latter disappearing, was succeeded by a constant pain at the articulation of the second rib on the left side. He was under treatment for some time previous to the taking of these notes, and had tried without success various remedies—iodide of potash, aconite, digitalis, &c., &c. The pain still continuing, and interfering with free respiration; preventing him from working or making any exertion, a blister 4 x 4 inches was directed to be applied to the chest. Mist. Pot. Iodidi, j.; aconite continued.

August 8th, 1871.—The blister acted energetically, and gave speedy relief to the pain. The blistered surface now nearly healed. Expresses himself, as able to go to work.

August 12th.—No return of the pain; resumed work.

Sept. 19th.—Again presented himself for treatment, being much troubled with cough and uneasiness about the chest. Physical symptoms continue the same as when last seen, with the exception of the murmur supposed to be systolic aortic, which is scarcely audible. Repeated the treatment by blister, and continued the iodide of potass and aconite mixture.

Oct. 8th.—Cough relieved, uneasiness of the chest gone. Feeling strong and well, he resumed work.

Nov. 4th, 1872.—On examining him to-day find the presystolic bruit heard in its maximum intensity at the articulation of the fourth rib on the left side, with the sternum, and the post-systolic aortic murmur by which the second sound is replaced are both well marked. Has never been troubled with any cough, soreness, or other unpleasant symptom since the last blistering, and he affirms that there is not a sounder man in Portlaw than he is at present.

Remarks.—The points worthy of notice in this case are —1st. The marked characters of the murmurs. 2nd. The absence of any enlargement of the area of dulness. 3rd. The slight amount of constitutional disturbance when compared with the extent of lesion which, on first thoughts, one would suppose necessary to the production of "bruits" of such a marked character as I have described. 4th. The change of character in the case of the aortic obstructive murmur when examined Sept. 19th, 1871. 5th. The relief from pain and all the symptoms, for the treatment of which he presented himself, by blistering, constitutional treatment alone having failed.

As a note, I would add, that although I have set the case down as one of valvular lesion, yet I still question whether it might not be one in which the seat of mischief was the *peri-* not the *endo-cardium.* An autopsy or the further progress of the case, can alone satisfactorily establish which it is.

◆

ON THE RELIEF OF PAIN BY THE CONSTANT GALVANIC CURRENT.

By H. Stanley Gale, M..B. Lond.

Miss B., a maiden lady of fifty, very thin and "meagered" but otherwise healthy looking. Had perfectly good health till four years ago, when in the evening about seven o'clock, she was seized with violent cramping pain in the bowels, and a "strong bearing-down pain." This lasted about one hour, and then disappeared completely. It recurred in about a week, and has come on regularly every three or four days from that time till now. She stated in May 4th, 1871, that she then suffered the most excruciating pain in the womb, and down the inner sides of the thighs. So severe was the pain, that perspiration would at times pour off her face "like rain." This came on pretty regularly every third day, lasting about four hours. She had been under the treatment at different times of four eminent London physician-accoucheurs. One said there was ulceration of the os, a second fibrous tumour, a third amenorrhœa, and the fourth a tendency to prolapsus. Neither one did her any good. She then took, on the prescription of a country practitioner, small doses of ext. belladonna, and hypodermic injection of morphia. These only gave temporary relief. The local application of heat seeming to do more good than anything.

Miss B. then came under my care. I did not examine her then, as she was tired of being meddled with. I applied to her in the ordinary manner, a current from four cells of Dr. Althaus' battery. The current was quite inappreciable to my own sensations, but the moment she felt it, she screamed out with pain, turned deadly pale, and passed almost into a state of collapse. A little brandy soon brought her round, but she kept her bed for three days, and was in much pain all that time.

I should have said that although she suffered so much, she was a cheerful and *particularly* strong-minded woman with nothing fanciful about her. I had difficulty in persuading her to undergo a course of galvanism after this, but at last she did. I then began with two cells, and increased by two cells every other day until I used thirty. The pain gradually diminished, and at the end of five weeks she was perfectly from free it. She had a slight recurrence about a month after, which was cured by one application.

I have never before met with any person so extremely sensitive to the current as this lady was at first.

Miss D., æt. 42, also a maiden lady, hearing of the relief which Miss B., had experienced at my hands, and suffering from pain in the pelvis and the thighs, which, however, was not nearly so severe, consulted me some time afterwards. The pain was more regularly periodic in character, and lasted a shorter time. It was relieved by quinine, but this caused most acute headache. I applied the constant current for about six weeks without the least effect. I then galvanised the sympathetic with six cells of Stöhrer's battery for one minute at a time, every morning. At the end of a week the pain had gone. It has recurred occasionally, but is readily cured by a renewal of the galvanic current.

It is but fair to say that many milder cases have undergone little or no benefit from the application of the constant current, still we shall, no doubt, in a little time, find out what cases are suitable, and meantime, I for one shall continue to use the constant current as one of the most wonderful and useful remedies we possess for the relief of pain.

Hyde Road, Manchester.

POPLITEAL ANEURISM CURED BY THE LIGATURE OF THE FEMORAL ARTERY AFTER FAILURE OF COMPRESSION.

Reported by Denis Walshe, L.K.Q.C.P.I.,

Senior Resident Medical Officer to the Chorlton Hospitals, near Manchester.

Edwin H., æt. 61, joiner, married, no family, was admitted into this hospital on the 28th August last. He was then suffering from what he supposed was rheumatism of the left knee. Upon examining the joint, however, I discovered a pulsating tumour somewhat larger than the closed fist, occupying the popliteal space, and which I diagnosed to be an aneurism. He gave the following history. About last April he began to feel some pain in the knee, and noticed a swelling there. To relieve this he applied fomentations, vinegar, hartshorn and oil, &c. He next began to feel some stiffness in the joint, and noticed that in coming downstairs he could not bear his weight upon the leg, and was obliged to step out with the *right* foot, and then bring the left down on the same step of the stairs. When admitted, he complained a good deal of pain both at the joint and down the back of the leg. I put him on iodide of potassium, with a quarter of a grain of morphia at bedtime. This treatment very soon relieved the pain. He also suffered much from indigestion, which was relieved by the mineral acids and gentian. A careful examination of his heart revealed no disease of that organ.

On the 19th of September I attempted a cure by digital compression, but as I had to rely upon his fellow-patients to compress the artery the attempt failed. As the tumour was not then increasing much, I tried large doses of Pot. Iod., but without any effect.

On the 3rd of October I tried compression with a pair of Skey's tourniquets, one being placed near the groin, the other about the middle of the thigh, and each being screwed up alternately. Being unable to stop by the patient myself, or to procure a competent person, to whom I could intrust the management of the tourniquets, this plan failed too. I made him keep the instruments on, however, for, although they did not compress the artery properly all this time, they still diminished the pulsation in the tumour, and at least prevented it from enlarging. On the 22nd of October I was obliged to remove them, as the skin showed signs of sloughing from the pressure. After their removal the tumour rapidly increased in size, and on the 4th of November, after consulting with Dr. Leech and my colleague, Dr. Law, it was decided to place a ligature on the femoral.

Accordingly, on November 6th I ligatured the femoral in the usual situation. The ligature used was of carbolised cat-gut, both ends being cut off close to the knot. The wound was closed with iron wire sutures, and dressed with carbolic acid. Three hours after the operation the left limb was nearly, if not quite, as warm as the right.

The patient recovered his appetite on the third day after the operation, and from that time to the present he has steadily progressed without the occurrence of one bad symptom. The wound healed by the first intention, with the exception of a small spot near its upper part, where the incision ran through a small slough produced by the tourniquet. When pressure was made around this spot a little discharge welled up from the bottom of it. This continued till the twenty-first day, when it entirely ceased. The patient is now able to get about the ward with a sling under the foot. The aneurism is gradually getting smaller and harder.

This operation has been performed so often for the cure of popliteal aneurism that this case would scarcely merit a place in your pages were it not that there are two points in connection with it that deserve notice. These are—

1st. The good effects of compression even when it fails to effect a cure, and—

2nd. The great advantage obtained by the use of a cat-gut ligature.

The tourniquet places the limb in the same condition with regard to the circulation in it, as if the artery had been tied. In this case the collateral circulation was pretty well established before the artery was tied (as evidenced by the speedy return of warmth to the limb) and, therefore the chance of gangrene was reduced almost to *nil.* The danger of secondary hæmorrhage was obviated by the use of a cat-gut ligature, which, according to theory, is absorbed without dividing the coats of the artery. Practice bore out the theory in this case, for I have seen nothing of the ligature and do not expect to. Gangrene and secondary hæmorrhage :—The two great dangers of the operation were therefore avoided, the one by the employment of compression, and the other by the use of cat-gut.

Hospital Reports.

MERCER'S HOSPITAL.

Penetrating Wound of the Abdomen; Extrusion of a Portion of the Great Omentum; Recovery.

(Under the care of Mr. MacDowell, F.R.C.S.)

John Kavenagh, a healthy-looking labourer, æt. 22, was admitted to Mercer's Hospital on Monday night, the 2nd inst., suffering from a penetrating wound of the abdomen, which he had sustained less than an hour previously to his admission. He stated that he had been drinking at a public-house, when, for some trifling cause, a dispute arose between him and a Norwegian sailor, whereupon the latter suddenly stabbed him with "a sort of dagger in the belly."

Upon admission to hospital the man was extremely blanched and nervous, and his pulse small, but there was no sickness of stomach or hiccough. He held both hands over the site of the injury, as if for the purpose of lessening the pain caused by the motions of the diaphragm and abdominal muscles in inspiration. His clothes, which had been transfixed by the instrument, having been removed, a wound in the abdominal wall, of about three quarters of an inch in extent was discovered. Through this opening a portion of omentum protruded, which was about the size of a hazel-nut. This latter did not include any portion of intestine that could be detected. There was no evidence, so far as an opinion might then be formed, that the intestine had been wounded, or that any extravasation had taken place into the peritoneal sac; nor did there appear to be sufficient grounds for the belief that any hæmorrhage had taken place into that cavity. The man's blanched appearance might fairly be accounted for by the natural dread he entertained of the consequences of the dangerous injury he had received.

The external loss of blood was certainly slight, as the man's clothes testified. The extruded omentum was of a livid colour, and it was moist from sero-sanguineous effusion, no doubt the result of strangulation; but there was no hæmorrhage or other indication of wound or mutilation of any kind.

Under these circumstances, and particularly having regard to the recent occurrence of the injury, and healthy state of the protruded structure, I determined to make an effort to replace the mass within the cavity of the peritoneum; accordingly, having bathed it with a stream of tepid water, I tried the taxis, observing the greatest gentleness in manipulation. This measure proved unsuccessful.

I now enlarged the wound with a curved probe-pointed bistoury, upon a director to the extent of about half-an-inch externally, and not more, I should think, than one-eighth of an inch at the internal stricture. There was but little blood lost by this proceeding, and the protrusion was reduced without difficulty, through both external and internal strictures—a fact of which I made myself certain by following it with my finger as it passed fairly into the peritoneal sac. The wound was drawn accurately together with strips of adhesive plaster, and these latter were supported by pads, maintained in position by fresh plaster strips. A broad and evenly-adjusted bandage was applied over all. No sutures were employed. It was directed that the patient should be kept constantly in a state of perfect quietude, and lying upon his back. In order to relax the abdominal muscles and to prevent traction upon the wound, I had his body slightly inclined forwards. His legs also were kept semi-flexed by pillows with the same objects.

He was ordered a draught containing thirty minims of tincture of opium and four drops of diluted hydrocyanic acid at once, and a suppository including one grain of opium every fourth hour afterwards. He was allowed to have, if awake, small quantities of beef-tea and ice every second hour. All solid food was forbidden. Next morning, eleven hours after the accident, I found he had had several hours of refreshing sleep, and that there was no sign or symptom existing to cause alarm. The opium, beef-tea, and ice to be continued. On the morning of the fourth day the wound was examined and found to be united by first intention. It was highly gratifying to observe that there was not the faintest evidence of peritonitis, or, it might be said, of even local tenderness. On the fifth day he had a natural evacuation from the bowels without inconvenience; the opium was discontinued; and on the seventh day he was discharged from the hospital quite well. He was directed to continue to wear the abdominal bandage.

The reparative powers of nature, as exemplified in this extremely interesting case, are admirable, and serve, at all events in some degree, to confirm the opinion which appears to be gaining ground, and which I have frequently seen verified in practice, namely, that the peritoneum, while it should not be meddled with unnecessarily, is not so much to be dreaded as surgeons were formerly wont to suppose, and that under proper after-treatment, judicious regimen, and fair hygienic conditions, wounds of this membrane will, in the great majority of cases, heal without any of the alarming symptoms we have been taught to apprehend.

29 York Street, Dublin.

Transactions of Societies.

THE MEDICAL SOCIETY OF LONDON.

Monday, December 9th, 1872.

T. Bryant, Esq., President, in the Chair.

INFANTILE PARALYSIS TREATED BY THE CONTINUOUS CURRENT.

Dr. Sansom treated the following cases by the current transmitted through the spine by the means of a large

Pulvermacher's chain:—1. E. P., æt. 2½ years, admitted into the North Eastern Hospital for Children June 26th, 1872; quite unable to walk, but irritability of muscles fairly good. Current for half an hour night and morning, mist. ferri and ol. morrhuæ. Improved, and on the fourteenth day discharged, able to walk quite well. 2. M. A. M., æt. 4 years, admitted 12th Sept. with inability to stand and rigidity of left arm with incurvation of the thumb. The child was rachitic; the condition had followed an attack of pertussis. Treatment—Mist. ferri, current down spine for half an hour night and morning, and after a fortnight current in addition for half an hour from nape of neck to palm of left hand. Great improvement followed. On Oct. 5th she walked very fairly, and very soon could run about the wards. Subsequently, at the Convalescent Home, she has been able to move her thumb at will. 3. E. C., æt. 3½ years, admitted Sept. 28th, unable to walk or stand, and no reflex action could be excited in the lower limbs. The condition followed an attack of measles. Treatment—Mist. ferri, liq. strychnia; current half an hour night and morning. Greatly improved, and on Oct. 12th could stand and walk by herself; on the 23rd quite recovered. Though the collateral treatment may have had a share in the production of these good results, it appeared to all who observed these cases that the galvanism contributed largely to the restoration.

Mr. Spencer Watson hardly supposed that a current could pass from the spine through the anterior cords by merely applying poles to the skin. He would like to know how the chain was applied.

Dr. Routh wanted to learn the influence iron and strychnia had exerted, and also the duration of the paralysis. If the patients got well in a year he thought the result good. He was satisfied with the chain, and considered also Stohrer's battery very useful.

Dr. Sedgwick reverted to Mr. Barwell's plan of injecting strychnia under the skin: he should like to know the opinions of the Fellows on this point. He should also like to hear more of the history of Dr. Sansom's cases, and thought we should seek higher up than the spine. The diseases often set in with cerebral symptoms.

The President thought the subject of Infantile Paralysis was one that called for more investigation. Where could he find reference to sclerosis of anterior column of spinal cord? Paralysis attacked groups of muscles, and was generally paralysis of motion and not of sensation. Electricity could scarcely be regarded as a means of removing sclerosis of the cord; it was injurious in the earlier stages, and only used by himself in the later. He thought the interrupted current the best. Iron and cod-liver oil were good in the early stages, and in the later strychnia and electricity.

Dr. Sansom, in reply, said to Mr. Watson that there could be no doubt that the current traversed the spinal cord. The cases were chronic, and his treatment was applied in the later stages of the disease. He would use Mr. Barwell's treatment in cases which did not yield to any other. He referred the President to the French edition of Niemeyer's work for an account of sclerosis of cord by M. Corniel.

Dr. Wiltshire mentioned that Mr. Charcot had worked at the subject of Sclerose en Plaques in connection with the pathology of ataxy, and referred the President to his writings. For his own part, thought the suddenness of attacks, and sometimes of recovery, indicated that occasionally, at least, cases were of reflex origin. Some patients got well of themselves, and he doubted whether sclerosis of the anterior column was a constant pathological change in such cases. Improvement of the general health was the chief thing to aim at. Electricity is valuable for keeping the muscles in action, so as to prevent fatty degeneration from disease.

Mr. Streeter showed an engraving illustrating the

TALIOCOTION OPERATION,

which was not uncommon in India, and had long been performed, originating during the Mahratta War, when it was the practice of Tippoo to mutilate his prisoners by cutting off the nose and the right hand, after which means were taken for restoration of the former.

The President brought forward a specimen of

FRACTURE OF THE NECK OF THE THIGH-BONE

from a woman 80 years of age, who died of erysipelas. There was really a vertical fissure of the neck of the femur, which was much rarer than impaction. The specimen showed all the progress towards formation of a false joint.

Mr. Adams said that it was an impacted fracture external to the capsular ligament.

Mr. Bryant said it was an extra capsular fracture of the neck of the bone by a blow from behind on the trochanter. Violent manipulations loosen the impaction and do harm.

The President also showed a very interesting case of

LARGE SWELLING IN FRONT OF THE SHOULDER.

The humerus could be rotated without pain or crepitation. The man, æt. 50, had been treated for rheumatic pains without good effect. The abscess was opened, and half a pint of semi-purulent fluid discharged. He died suddenly after four days' illness. It was a case of acute disease of the joint producing slight symptoms.

December 16th, 1872.

TRAUMATIC PERICARDITIS.

The patient was accidently stabbed while playing with a companion, the knife entering the chest close to the upper border of the sixth rib, and penetrating half an inch in depth. On recovering from the shock of the accident, symptoms of pericarditis were apparent, supervened with a transient friction bruit, and signs of moderate effusion. A few days later it was evident that a considerable quantity of fluid had accumulated in the left pleural cavity, but recovery was rapid and uninterrupted, and the patient was enabled to return home twenty-one days after he first came under notice. In considering the practical bearings of this case, Dr. Farquharson first referred to the very rapid disappearance of the friction bruit, and stated why he considered this due to moderate effusions in the sac, rather than agglutination of the surfaces of the membrane. The quality of the fluid in the left pleura was next discussed, reasons were assigned for the belief that it consisted of blood, and in making a few concluding remarks on treatment, rest, quiet, and avoidance of all disturbing causes, were believed to be the true indication.

Mr. Bryant referred to Dr. Fisher's able paper on the subject, and said these cases usually did pretty well. There was no exact analogy between traumatic and other cases of pericarditis; he would use ice and such like, but neither antimony or calomel.

Dr. Symes Thompson asked whether in these cases blood escaped with pericardium and separated into clot and serum, the latter being absorbed. He referred to a remarkable paper by the late Dr. Stroud, who speculated on the physical causes of the death of Christ. He agreed generally with Dr. Farquharson.

Dr. Routh would have given the patient small doses of turpentine as an astringent and as a stimulant. If blood did escape quickly and in quantity; the separation referred to by Dr. Symes Thompson, occurred, but if guttative, it did not do so. He would scarcely suppose much blood escaped into the pericardium in Dr. Farquharson's case. The treatment for pericarditis should be much the same whatever its origin. He would use ice locally.

Mr. William Adams mentioned a case which had come under his notice. A man had fallen on a small chisel which punctured the heart. After a long collapse the man recovered.

Dr. Wiltshire asked what became of the solid portion of the clot referred to by Dr. S. Thompson.

Dr. Symes Thompson said that he thought life was usually but short after the escape of much blood, and knew of no evidence of what became of the clot.

Dr. Farquharson thanked the Fellows for their suggestions, and had he known the value of turpentine in shocks, he would have used it.

Mr. Brudenell Carter showed a man who illustrated the advantage of a new operation for cataract, which was devised by Dr. Taylor, of Nottingham. This operation would, he thought, supersede most other operations for cataract, scarcely any irritation of the eye was produced. He related details of cases upon which he had performed this operation, and showed some drawings.

The President asked whether the opening in the iris was elastic, in reply to which Mr. Carter said no, but the openings in the iris and in the cornea were co-extensive; there was but little hæmorrhage.

Mr. Davy asked whether the pupil was mobile and the vision good.

Mr. Carter found the mobility perfect and the vision was good when the tissues of the eye were sound.

Mr. H. R. Hardy enquired whether Mr. Carter had tested the mobility of the iris by atropine, and what he thought of ether in eye operations.

Mr. Carter had used atropine and fully dilated the pupil. As regarded ether, he had not found it relax the muscles sufficiently. Mr. Joy Jeffries, of America, had given ether with perfect success for him; at St. George's Hospital much ether was used. He had since used ether with satisfaction, and would not, if he could avoid it, return to chloroform.

Mr. Richard Davy showed the pelvis of a man, æt. 43, who, having fallen ninety feet in May, 1871, died a few hours after of internal hæmorrhage. The left auricular facette of the sacrum was completely broken off and dislocated upwards with the left ilium, the symphysical end of the left ilium was half an inch higher than the right, but the osseous abrasion at this part was very slight. The left sacral margin, and left lumbar transverse processes were roughly rasped off; the coccyx was pulverised, and the left femur simply comminuted, the right rami of the ischium and pubis were fractured on their pelvic aspect only. Mr. Davy mentioned that the sacro-iliac articulation preferred fracture of the sacrum to ligamentous separation, whereas the symphysis permitted dislocation. The sacrum had six vertebral coalescences.

The President thought the specimen shown resembled generally those of vertebra when the bone gave way rather than the ligaments.

Dr. Routh said he had known the sacro-iliac cynchondioses separate in women after labour.

Mr. Braine asked whether these patients recovered, when Dr. Routh answered in the affirmative.

Mr. Royes Bell showed a specimen of a tumour occupying the lower and inside part of the right forearm just above the wrist. On dissection it appeared to spring from the ulna artery and to involve the lower end of the ulnar bone; it was about the size of a Tangerine orange, and projected in front and behind the forearm. There was ulceration where a puncture had been made in its anterior aspect; behind it was covered with skin, discoloured in places, and superficially ulcerated here and there. The specimen had been hardened in strong spirits so that it appeared firm, but at the time of operation it was clothed with blood. The patient from whom it had been removed was a woman, æt. 61, she suffered with it five years; frequent hæmorrhage had taken place from the opening caused by a puncture in front. Its origin was attributed to a blow.

Mr. Bryant thought it was a very uncommon specimen of a blood cyst, for the end of the ulnar had been partially absorbed. The whole subject of cysts in bone was of great interest. He related a case in point.

Mr. Davy asked whether the limb should be removed summarily or an exploratory incision made.

Mr. Bryant preferred the latter.

Mr. Bell would also have preferred the exploratory incision if it had appeared desirable, on the whole, he and his colleagues thought amputation was demanded.

STUDENTS' COLUMN.

SYNOPTICAL REVIEW OF THE OFFICINAL PREPARATIONS OF THE BRITISH PHARMACOPŒIA.

By W. Handsel Griffiths, Ph.D., L.R.C.P., L.R.C.S.Edin.,

Assistant-Librarian Royal College of Surgeons in Ireland.

TROCHISCI (LOZENGES).

This form of administration is adapted to such medicines as may be given in small doses and which have not a disagreeable flavour.

There are ten formulæ for them,—viz.:—

Trochisi Acidi Tannici.
„ Bismuth.
Trochisi Catechu.
„ Ferri Redacti.
„ Ipecacuanhæ.
„ Morphiæ.
„ Morphiæ et Ipecacuanhæ.
„ Opii.
„ Potassæ Chloratis.
„ Sodæ Bicarbonatis.

The following table gives the composition and strength of each:—

	Each contains.	Active Ingredient.	Extra.	Refined Sugar.	Gum Acacia.	Mucilage of Gum Acacia.	Distilled Water.
				oz.	oz.	oz.	
T. Catechu	1 *gr. of Catechu*	Pale Catechu, 720 grs.		25	1	2	q. s.
T. Ferri Redacti	1 *gr. of Reduced Iron*	Reduced Iron 720 grs.		25	1	2	q. s.
T. Ipecacuanha	¼ *gr. of Ipecacuanha*	Ipecacuanha, 180 grs.		25	1	2	q. s.
T. Potassæ Chloratis	5 *grs. of Chlorate of Potash*	Chlorate of Potash, 3,600 grs.		25	1	2	q. s.
T. Sodæ Bicarbonatis	5 *grs. of Bicarbonate of Soda*	Bicarbonate of Soda, 3,600 grs.		25	1	2	q. s.
T. Acidi Tannici	½ *gr. of Tannic Acid*	Tannic Acid, 360 grs.	Tinct. of Tolu, ½ oz.	25	1	2	1 oz.
T. Morphiæ	*1-36th gr. of Hydrochlorate of Morphia*	Hydrochlorate of Morphia, 20 grs.	Tinct. of Tolu, ½ oz.	24	1	2	½ oz
T. Morphiæ et Ipecacuanhæ	*1-36th gr. of Hydrochlorate of Morphia and 1-12th gr of Ipecacuanha*	Hydrochlorate of Morphia, 20 grs., Ipecacuanha, 60 grs.	Tinct. of Tolu, ½ oz.	24	1	2	½ oz.
T. Opii	*1-10th gr. of Extract of Opium*	Extract of Opium, 72 grs.	Tinct. of Tolu, ½ oz., Extract Liq'rice, 6 oz.	16	2		q. s.
T. Bismuthi	2 *grs. of Subnitrate of Bismuth*	Subnitrate of Bismuth, 1,440 grs.	Carbonate of Magnesia, 4 oz., Precip. Carb. of Lime, 6 oz., Rose water, q. s.	29	1	2	

It will be noticed that the first five of these lozenges have no extra ingredients, and, moreover, that the proportion of refined sugar, gum acacia, mucilage, and water, is the same in each case. It will also be presently shown that the directions for the preparation of each of these lozenges are the same. The next four lozenges in the table have ½ oz. of tincture of tolu as an additional ingredient. Extract of liquorice is used in *Trochisci Opii*, in lieu of the mucilage, and rose water is substituted for distilled water in *Trochisci Bismuthi.*

The following direction for preparation applies to all the lozenges, except *Trochisci Acidi Tannici, Morphiæ, Morphiæ et Ipecacuanhæ*, and *Opii.*—

"Mix the dry ingredients, and add the mucilage and water to form a proper mass. Divide into 720 lozenges, and dry these in a hot-air chamber with a moderate heat."

In the preparation of *Trochisci Acidi Tannici* and *Trochisci Morphiæ*, the active ingredient is first dissolved in the water, the tincture of tolu and mucilage mixed are then added, and, finally, the gum and sugar also previously mixed. In *Trochisci Morphiæ et Ipecacuanhæ* the same process is performed, but the ipecacuanha is to be mixed with the gum and sugar. In *Trochisci Opii* the extract of opium is to be moistened with a little water, and added with the tincture of tolu, to the extract of liquorice heated in a water-bath; when a proper consistence is obtained, the mixture is to be incorporated on a slap with the sugar and gum previously mixed.

REGISTERED FOR TRANSMISSION ABROAD.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 1, 1873

THE NEW YEAR.

TO-DAY we begin a New Year, and at the same time a New Volume. We shall not attempt a complete Retrospect of the year just gone by, nor shall we attempt to penetrate the prospect before us. It will suffice to mark the occasion with a few reflections respecting it, bearing on Medical topics, and so start each reader on his own musings.

Few things come so near some of us as the losses we have sustained through death, and the Obituary Record of the Profession for 1873 is a sad one. As we write we hear the melancholy story of the decease of Mr. Holmes Coote, Senior Surgeon of St. Bartholomew's Hospital, and who discharged the duties of other highly responsible positions in the Profession for many years. It is most melancholy to think that he, who for so many years did Lawrence's duty at Bethlehem, should have expired in an Asylum, and that his offspring should be in want. Surely the Governors of the Royal Medical Benevolent College will not hesitate to vote for the son of such a man now he is a candidate for admission to their school.

Among other names of men who have died in the year we may recall:—Dr. Aldis, Dr. James Baker, Dr. Cowdell, Dr. George Edward Day, Mr. Thomas Heywood, Dr. Augustus Bozzi Granville, Henry Curran, Dr. William Henderson of Edinburgh, Mr. Thos. Hewlett of Harrow, Dr. Thomas Barnes of Carlisle, Mr. I'Anson of Newcastle, Mr. Bickerton of Liverpool, Sir Andrew Smith, K.C.B., Frederick Carpenter Skey, Alfred Poland, Dr. Neil Murray, S. Jeyes, M.D., Dr. Renton, Dr. Mackesy of Waterford, Dr. John Neil of Croydon, Dr. Duguid, Dr. Archibald Simpson, and Dr. Walpole, &c., &c.

The loss of Louis, even at a ripe old age, is one that affects the Profession everywhere. His work was done, but he lingered long, and his removal breaks a tie with the past that was pleasant to know existed.

Laugier, too, is a name no more among the living, and by some few will be missed as much.

But why linger on this, the part of our Retrospect most full of regret? With the new year we must begin a new round of duty, and if we cannot equal may do our best to help supply the places of those who have finished their career.

As journalists we may be expected next to allude to the legislation of the year. The passage of the Public Health Act signalises 1872, in spite of all its imperfections. These, indeed, we had anticipated, and again we protest against the manner in which it seems likely to be administered.

If the Government had intended to show their contempt of Medical men they could have selected no more effectual way than to ignore them in a great legislative Act on Public Health, and if the Local Board desired to imitate their superiors they could scarcely do it more effectually than by committing sanitary inspection to lawyers or other hangers on to the exclusion of the only Profession that could be supposed to possess information on the subject.

This, however, is the way in which successive Governments have behaved to the Medical Profession, and in spite of all the boasts of its supports, the present cabinet seems to be destitute of the courage to do an act of justice that would be really popular.

It is all very well to say that a K.C.B. and a baronetcy have been given to those who were called to attend a prince, but such honours would have been as well declined when it has transpired that they would leave others as well deserving of their country unrecognised.

We averred at the time that Jenner should have been made a peer; but it seems that a Government which has no hesitation in sending any number of lawyers into the Upper House to make way for others is absolutely afraid to let medicine be there represented. And worse than this other distinctions half promised by the party long ago remain unconferred. Verily, medicine has not much cause to care for the gentlemen who rule the country, and favour physic with no notice, except in the income-tax schedule.

But, have we not a petty parliament of our own—yclept—General Medical Council?

We had almost forgotten that. It seems to do so little. As a talking machine it is, indeed, a representative of parliament that may serve to parody them; but a glance at its year's work shows that it has done but little.

It met, indeed, and took into consideration, the subject of Conjoint Boards. It approved the scheme of the English boards as far as it went, and we are obliged to confess it was not complete. It then postponed action for the Sister Kingdom, and what is the result? It is nearly a year since the meeting, and some expect another session will soon be opened with no better result than the former. Ireland, indeed, has a plan, and that may be approved; but the Scottish bodies make no sign, and probably will not.

Are we all to wait their pleasure, or must other means be found to compel them to unite?

All this seems as uncertain as the hope of comprehensive legislation, for which so many have been willing to wait so long. For ourselves we may as well confess that we look forward to the year now opening before us with as little hope as we did a year ago to that which has thus slipped away.

There are, however, cheerier subjects. The progress of medicine and the allied sciences has not been hindered, and if the Profession has gained nothing politically, it has in these things which are so much higher.

As it would be impossible to give a statement of all these in the space at our command, we need only say they have been all represented in our pages; and we hope to make the Medical Press of 1873 as good as, or better than, it has been in 1872, or in any of the thirty-five years in which it has pursued its work.

THE METHOD OF ELECTION IN THE IRISH COLLEGE OF SURGEONS.

The election of a successor to Mr. Hargrave, in the Chair of Surgery in the Irish College of Surgeons, recorded in another part of our issue, ought not, we think, to be permitted to pass without some further consideration as to the expediency and equity of the method of proceeding which, under the authority of the charter, is adopted in the selection of Professors and Examiners in the College. In discussing the subject we desire it to be understood that we have no intention either of quarrelling with the choice which has been made, or implying in the electors anything but a perfectly honourable discharge of their duty; and in condemning the system we do so not at all because it has resulted in the selection of Mr. Wilson, Dr. Little, or Mr. Stokes, but because in these three elections the haphazard and untrustworthy characteristics of the procedure have been abundantly manifested. The following is the clause of the charter which settles the method of election:—

"Whenever and so often as it shall be necessary to elect an Examiner or a Professor, the President or Vice-President, together with not less than two-thirds of the said Council, shall meet and assemble together, pursuant to a special summons in that behalf to be issued and transmitted as aforesaid, three clear days at least before such meeting and assemblage; and being so assembled shall choose and appoint by lot seven members of such Council, or as near thereto as may be; which said persons so chosen and appointed, shall proceed forthwith to elect by a majority of voices, such Examiner, provided the said members of the Council, so by lot appointed, shall find among the candidates for the said offices of Examiner or Professor a person or persons having such qualifications as the Council may from time to time determine by bye-laws to be necessary, and also being in their judgment, or in the judgment of a majority of them, fit and competent to discharge the duties of said office of Examiner or Professor, as the case may be: and the said members of such Council, so by lot appointed or chosen, shall thereupon make and subscribe the following declaration:

"'I,   do solemnly and sincerely promise and declare that I will, to the best of my knowledge, skill, and judgment, without hatred, evil will, partiality, affection, favour, or fear, justly, equally, and faithfully discharge the trust now reposed in me to elect the most fit and proper person to fill the situation of Examiner or Professor of   . And further, that I consider myself bound to elect the candidate who affords the most unquestionable proofs of good character and of ability, acquirements, industry, and perseverance applied to the branch for which I am now called upon to elect a Professor or Examiner; and that I do not consider previous services in the College, in this or any other department as establishing a peculiar claim to a preference. And also, that I have not, directly or indirectly, promised to vote for or favour any particular candidate.'

"And such declaration shall be duly administered to them respectfully by the President or Vice-President, or any member of the Council who shall be then present, and such declaration shall be taken, and such appointment by lot of seven members, to make such election, shall be made at a meeting of the Fellows of the College duly convened as hereinbefore provided."

We presume that the intention of this enactment was to defeat the exercise of influence by persons who might have the advantage of previous official connexion with the College, and, as far as possible, to throw open the Professorships and Examinerships to outside competition. It does not seem, however, that it has at all served this purpose, for we are aware that personal canvas is pursued as actively as possible. We object to the system, firstly, because it takes away from two-thirds of the Council the power to give effect to their opinion, and, secondly, because it makes so grave an issue the subject of a sort of pitch-and-toss. In two of the three elections to which we have referred it was strongly believed that an individual candidate would be supported by a large majority of the Council, and accordingly the chances ran high in his favour. By the fortune of the lottery-box, however, the forecast was completely reversed, and the favourite candidate was beaten. We think we are justified by the opinion of the Profession in Dublin in saying that, assuming that the best man was in each case chosen, nevertheless the seven persons on whom the lot fell did not in either case fairly represent the voting of the Council at large, that if every member had voted the result would have been different.

A method of election which may make a Professorship the subject of a "fluke" cannot be defended and ought not to be perpetuated. The success of a candidate ought to depend solely on his merits. He should know exactly the jury by whom the verdict will be given, and he ought not to be encouraged to hope for a cast of the die which will be altogether in his own favour.

Another point will, we think, require adjustment before the next election takes place. When the seven electors retire to their jury-room are they to give their votes *viva voce* or by ballot? The clause of the charter quoted above, which provides that they shall elect "by a majority of *voices*," would appear to indicate that the method should be uniform in all cases. With the ballot vote it is plain that the unfriended candidate will have a much better chance of success against a competitor who is backed by influential support. In these matters the Council have no power other than to interpret the law. We shall look forward to the time when this, with other well-known blots, may be erased from the charter.

THE "MEDICAL PRESS" FORTNIGHTLY RETROSPECT.

The world of medicine runs round so rapidly in these times, and the additions to the armamentarium of the physician and surgeon are so numerous and ever recurring that the taste of the Profession in matters of Medical journalism is materially affected by it. The prolix scientific discourse is now relegated usually to the "heavy" quarterlies, and the weekly periodicals devote themselves specially to short papers and reports, and to brief gleanings from the hebdomadal harvest of medicine and surgery.

That we may keep pace with this growing taste, we have made arrangements for the publication each fortnight during the coming year, of a complete Retrospect of the Medicine, Surgery, Obstetrics, and Pharmacy of all countries and languages. We shall devote considerable space to this new Department of our Journal, and we shall endeavour to make it terse—practical, accurate—and acceptable to our readers. The compilation of this Fortnightly Retrospect is in the best hands, and we shall feel much surprised if the contributions will not do justice to the Editors and to the Medical Press.

THE OPHTHALMIC CONGRESS AND OPHTHALMOLOGY.

III.

Quacks and quackery are everywhere fattening and preying upon the public, and who will put them down? cries Dr. Warlomont. It almost surpasses belief that, approaching as we are to the latter part of the nineteenth century, people of education, as much as the illiterate clodhopper, still give every encouragement to the absurdities of the itinerant quack doctor, and are willing to bleed freely in their purses. We blush to find this detestable fraternity of cheats maintain their footing among civilised nations. Yet such is the fact, for Dr. Warlomont utters a fierce and indignant remonstrance against a race of quack oculists, still flourishing and numerous on the Continent, wandering, he tells us, from town to town and from village to village, and driving a thriving and nefarious trade, or holding their motley revels in the taproom of the small public-house. This disgraceful kind of practice in Germany is not confined, as in this country, to men without a particle of knowledge of medicine or of surgery, but it is practised also by a higher class, men who hold diplomas from some recognised university, and who occupy at stated periods some more elevated or lucrative place in society. Many having some standing do not scruple to make periodical visits to country towns, the more fashionable places of resort, and in an artful manner take care to have their wonderful skill blazoned forth, and with a flourish of trumpets the coming man is duly announced—men who do not scruple to resort to the meanest of tricks to attract and secure a patient.

Such a poacher on other's preserves is adroit,—"You must submit to an operation, must you, says Dr. So-and-so, does he? Well, wait a little, and try my wonderful skill, and perhaps you will escape his knife, which, in confidence, is said not to be a very skilful one." The victim falls into the trap, and is imposed upon by various strange devices and wonderful applications; weeks pass away and no benefit is obtained, and reluctantly he submits at last to be operated upon, and ultimately finds himself mutilated and robbed. But this matters little to the wonderful practitioner, who passes on to the next town to find and secure another dupe. Unfortunately, this kind of practice often wags well with a class of men who dishonour their calling. Cannot the Ophthalmic Congress do something to put them down? asks Dr. Warlomont. The passing of a stringent rule, and entirely excluding them from holding any place among men of science, or from appearing at the Congress. But would this have the effect of lessening the evil? Such men are no longer amenable to rules which govern those whose *mens conscia recti* is above all price and money-getting, and who set some value upon the good opinion of their fellow men, and are far above all baser considerations. The still and small voice of conscience left behind is seared and hardened to a degree not likely to feel the prickings of the sharp but delicate needle employed by the oculist. But quite apart from this, some regard should be had to the drained purses and damaged eyes and health of the victims of such a system, although people voluntarily and with eager credulity offer themselves to be despoiled, and scarcely deserve sympathy. We, however, heartily join Dr. Warlomont in his manly protest against the existence of a state of things most discreditable to the judgment, science, and learning of our time. His feelings are the more keenly excited on the subject from having just returned from an atmosphere which he believes to be freer from the dishonest doings of the charlatan fraternity than his own; but we fear the difference between us is only in degree, and that we are no better off in this respect than our neighbours.

◆

Notes on Current Topics.

The Professorship of Surgery in the Irish College of Surgeons.

The election of a successor to Mr. Hargrave was held on Tuesday, the 24th ult., in the Board room of the College. The competitors for it were Mr. Henry Gray Croly, Surgeon to the City of Dublin Hospital; Mr. William Stokes, Surgeon to the Richmond Hospital, and Lecturer in Surgery in the Carmichael School; Mr. J. K. Barton, Surgeon to the Adelaide Hospital, and Lecturer in the Ledwich School; Mr. Corley, Surgeon to Jervis Street Hospital, and Lecturer in the Carmichael School; Dr. Nugent, formerly of Drogheda, and now Examiner in Arts in the College; and lastly, Dr. F. Thorpe Porter. As the issue of the Medical Press and Circular was despatched within an hour of the termination of the election it was impossible for us to communicate the result to our subscribers.

The President, Dr. F. Kirkpatrick, having taken the Chair, and the Letters of Application having been read by the Secretary of the College, Mr. Colles, the selection by lot of seven from the twenty-one members of Council was proceeded with as provided by the Charter. The lot fell upon the following Councillors:—The President, Dr. Kirkpatrick, Mr. Porter, Mr. Smyly, Dr. MacNamara, Mr. Adams, Dr. Robert McDonnell, and Mr. Edward

Hamilton, who retired to deliberate, and after a lengthened absence declared Mr. William Stokes to have been elected. In this election, for the first time, the exhibition of preparations, apparatus, casts, and drawings, contributed by the candidates from their own practice, was made a part of the ceremonial.

Alcohol.

Tweedie's "Temperance Year-book of Facts and History," for 1873 contains a full account of the Licensing Act for 1872, the evidence on habitual drunkards given before the Select Committee of the House of Commons, and a variety of other useful information. The Profession will be interested in the careful epitome of the discussion caused by the now famous Medical declaration on alcohol. The discussion on alcohol started by Dr. Dickenson, is another indication of the attention this subject is exciting.

Veratrum Viride in Hæmorrhage and Aneurism.

Dr. H. N. Eastman, of Geneva, N. Y., has successfully employed veratrum viride as a sedative in pulmonary hæmorrhage, when no acceleration of the heart's action was present, for the express purpose of reducing the *normal* circulation to the lowest point compatible with the safety of the patient, for the sole object of giving the pulmonary vessels rest, so to speak, to distend them as little as possible with the incoming blood, and thus prevent further rupture of the capillaries of the part, and afford an opportunity for the vascular lesions already existing to be obviated, by temporarily reducing the normal circulation. In the veratrum viride we seem to have just the article to hold the heart temporarily, to lay our hand on that organ, as it were, and thus restrain its action while the pulmonary capillaries have time to recover their tone, and the ruptured branches to unite, and that, too, without detracting from the vessels an ounce of blood or depressing the vital energy on the one hand, or doing any considerable injury to the digestive apparatus on the other, since it is ordinarily unnecessary to produce nausea or intestinal irritation in order to secure the full sedative influence of the veratrum if judiciously administered.

Dr. J. W. Collins, in the *American Practitioner* and the *Medical and Surgical Reporter*, says :—

"After an extensive use of the drug in different forms of hæmorrhage, I am thoroughly satisfied that it possesses the property in a very remarkable degree. I esteem it the promptest as well as the most reliable of all our means for controlling both active and passive hæmorrhage. The first case in which I had occasion to test the hæmostatic powers of veratrum was one of hæmoptysis, which had resisted all the usual remedies, but yielded almost at once to five drops of Norwood's tincture, given every hour for six hours. It is worthy of remark that the tolerance of the drug was very striking in this patient, the large quantity given having produced neither nausea nor other unpleasant symptoms. The next was one of aneurism of the left subclavian artery, the result of an injury to the vessel in its second part, or just behind the scalenus anticus muscle, from the small blade of a pocket knife. The tumour was about the size of a hen's egg, and involved all the second portion, and probably the first also, of the vessel. It was accompanied by the characteristic thrill, pulsation, pain in the shoulder and arm, absence of radial pulse, coldness of the limb, &c. Not deeming an operation advisable, and digital or other compression being impossible, I determined to give the veratrum, in the hope that it might so lower the action of the heart as to favour the formation of a coagulum in the aneurismal sac. I began with five drops, increasing the dose by one drop every third hour, until the full sedative effect of the medicine was produced. I continued it, in doses of from five to twelve drops, for ten days, at the end of which time the tumour had almost entirely disappeared, a small, hard lump only remaining, with very slight pulsation, no pain in the arm, no thrill, and considerable pulse at the wrist. The patient, a stout young negro, thinking he was well, quitted me, but returned at the end of two weeks, with most of the symptoms as well marked as at first. I put him on the same treatment, and continued it for fifteen days, the last six days merely to make sure of a cure, for the tumour, with all the attending symptoms, had disappeared, the radial pulse had become normal, and the natural temperature of the extremity restored. At the end of twelve months I saw him again, when he informed me that he had been uniformly well.

"In epistaxis, seemingly independent of the cause which gave rise to it, the veratrum has been in my hands uniformly successful. It has been equally so in menorrhagia, active or passive. In a case of secondary hæmorrhage, occurring on the third day after amputation of the cervix uteri, I believe the remedy saved my patient's life. It has unfailingly arrested the hæmorrhage which has occurred in two cases of uterine carcinoma now under my care, and in one of these without at any time producing the least nausea. Indeed, the control which it exercised over the floodings, which had previously worn the patient almost away, has allowed her to actually gain in both flesh and strength, and awaken in her mind the delusive hope that she will recover. My friend, Prof. J. T. Gilmore, of Mobile, informs me that, at my suggestion, he used the veratrum with entire success, after other means had failed, in a secondary hæmorrhage following amputation of the thigh; also in a case of epistaxis, which was so obstinate as to threaten life. Dr. Gilmore further says that the veratrum, given in doses of fifteen drops, is regarded by the Profession in Mobile as being the most efficient remedy in certain cases of puerperal eclampsia. I myself have not had an opportunity of using it in such conditions, but do not for a moment doubt that it would prove a most reliable agent in a certain class of these cases. I have seen the best results follow its use in the periodical hæmorrhages which occurred in two cases of placenta prævia. It should be given in doses of from three to fifteen drops, repeated every one, two, or three hours, according to the urgency of the case, always carefully watching its effects."

The editor of *Cosmos* says—"The remedial influence of veratrum in such cases would doubtless be greatly enhanced by the addition of ergot to contract the vessels, and turpentine or other styptic to increase the plasticity of the blood, with sometimes morphia to allay undue excitement in active disorder, or in passive conditions such stimulants as electricity and strychnia to excite tonicity of the tissues implicated, and strengthen the general system."

A Pin retained in the Throat fourteen months.

In the *American Journal of the American Sciences* we find the following case related by Dr. A. Ady, M.D., of West Liberty, Iowa :—

I was called to J. W., May 11th, 1872, who stated that fourteen months previous he had got a pin in his throat. It was attended with considerable pain and loss of voice. After an interval of some two weeks, efforts were made by an intelligent surgeon to remove it, but it could not be found. His voice gradually returned, so that in three months he could talk distinctly. The pain and soreness abated somewhat, but were never entirely absent. About three days before I called, his throat commenced troubling him more than usual. He experienced a feeling as though the pin was loose in his throat, and by the time I saw him he was suffering acutely. Passing my finger down his throat I felt the point of the pin extending forwards from the lower part of the posterior wall of the pharynx. It projected upwards at an angle of about thirty degrees, the point resting against the arytenoid cartilages. The head was firmly imbedded in the pharyngeal wall. I made several attempts to remove it with a pair of common œsophagus forceps, but they would not hold tight enough. I then took a small pair of polypus forceps, and slipping them down over the blades of the outer forceps as near the pin as possible, I succeeded in grasping it tight, and pulled it out. The pin was found to be $1\frac{3}{8}$ inch in length. For the space of an inch from the point it was corroded; the rest, including the head, was bright, showing how much had been imbedded in the tissues. The pin must have left the pharynx and travelled through the neck to some extent. It was evidently not in the pharynx or the œsophagus when its removal was first attempted, for the sponge probang was passed the whole length of the œsophagus without encountering anything. Sticking into the throat point foremost, would indicate that it had made a circuit great enough to reverse ends. Patient complained for some months, during the time that it was retained, of severe pain along the course of the omohyoid, which would look as though the pin had been in contact with the descendens noni nerve.

Jolly on the Dangers of Chloral Hydrate.

We have reported so many observations from various sources on chloral that we may well add the following summary of Jolly's paper in the *Bayer. Aertz. Int. Bl*, 1872, No. 12, from the last issue of the *New York Medical Journal.* In the course of two years, during which the author employed chloral hydrate in diseases of the mind, he observed two cases in which death occurred suddenly after the use of five grammes at one dose, which is much below the ordinarily employed maximum doses; the preparation presented in both cases all the characteristics of chemical purity. The psychical phenomena in both patients were preceded by a state of acute excitation, without any symptoms of paralysis, in one case from abuse of alcohol, in the other from unknown etiological causes; during life the patients presented no contraindication against the employment of chloral. The one, after receiving for four days at evening 5·0 grammes, expired with the fifth, a few moments after the administration of a similar dose, with instantaneous stand-still of the movements of the heart and of respiration; the *post-mortem* showed anæmia of the brain, acute œdema of the lungs, abnormal congestion of lower abdominal organs, completely normal heart, the vessels intact, blood dark and thin. The other had for twelve days received 5·0 grammes, with normal hypnotic effects, after a short stage of excitation; on the thirteenth day he sank a quarter of an hour after the administration of a similar dose, and expired after a few rattling inspirations. The *post-mortem* in this case presented only an extensive œdema of the lungs, thin fluid blood which was normally distributed in the organs; the heart, however, was large and flaccid, its muscle pale but not friable. In concluding these observations of his own, the author sums up all that is known thus far of the toxical phenomena caused by the continued use of chloral hydrate, and attributes them to the following three causes which have been proved experimentally to follow the use of chloral:—1. To the retardation of respiration, which may finally become stertorous, and cause stupor, coma, and death. 2. To the paralysing influence upon the vaso-motor nervous system (the insufficient innervation of the cutaneous vessels produces erythema, petechiæ, &c., in the use of chloral). 3. To the direct paralysing action upon the heart itself and its contractibility. The sudden occurrence of this last cause of death by paralysis of the heart was also present in the author's cases.

Ether.

We must direct the attention of our readers to Dr. Morgan's Address on the Ether question, which has been brought by him before the Surgical Society of Ireland, and which appeared in our last issue. The subject attracted unusual interest, and a Special Committee has been appointed to investigate the relative merits of both ether and chloroform, and to scrutinize the results of their administrations in Dublin.

The Committee met on Saturday last, and have framed a system of investigation throughout the Dublin hospitals which promises to secure the co-operation and attention of the Profession.

The Half-Yearly Abstract.

We have received the Half-Yearly Volume, edited by Dr. Dowell Stone, and find it as full as its predecessor of select extracts. The Appendix this time contains the abstract of Professor Humphry's lectures from our own columns, and also Dr. Hartshorne's Vaso-motor Physiology, also from the Medical Press.

Diaries.

We have before us Letts's Medical Diary for the New Year, in which we find besides their well-known arrangement for entering visits, some useful tables of poison, metric weights and measures, &c. We have also the Monthly Professional Diary of the same firm, which seems to us specially adapted to all who dislike to carry a pocket-book. Here, small enough even for a vest pocket, is all they can want for one month, and the twelve fit into a neat case to keep.

Typhoid Fever at Birmingham.

Such is the alarm created by the spread of this disease in the minds of the inhabitants in some districts around Birmingham, that an exodus has commenced in magnitude as to be almost termed a panic. On Friday a public meeting was held, at which it was stated, on the authority of the Medical officers of the Moseley district, that there existed nearly 50 cases of fever in 400 houses. For many years the imperfect drainage of Birmingham has been patent to all versed in sanitary matters, we therefore sincerely hope that the present state of things will compel those whose business it is, to at once adopt such measures as will, humanly speaking, prevent a recurrence of such a calamity.

On Measuring the Chest.

Dr. Frœhlich, of Dresden (*Virchow's Archiv.*), gives for chest measurements the following simple directions, attention to which would insure uniformity of procedure: The person to be examined should stand in an unconstrained position before the physician, breathing with his mouth shut, and should raise both arms, stretching them out horizontally. A tape not broarder than 1 Cm. (about ⅜ of an inch) should be placed round the chest directly under the inferior angles of the scapulæ behind, and the nipple in front, and should then be read off, first after the deepest inspiration and then after the deepest expiration, and both data recorded. The author then sums up the results which he has obtained by this method of observation, of which some of the more important are as follows:—The average circumference of the chest measured in 725 healthy men, 20 years of age, was, after deepest inspiration, 89 Cm. (about 35 inches), and after deepest expiration, 82 Cm. (about 32½ inches), the average play of the chest being thus 7 Cm. A circumference of only 75 Cm. (29½ inches) indicates what the author calls an unripe chest, and should exclude the person from military service A circumference of 750-759 Mm. should, under exceptional circumstances, be considered sufficient for milatary service; but when it reaches 760 Mm. (30 inches), if the person is otherwise healthy, then it ought to suffice.

The Brown Institution.

The Senate of the University of London, has passed the following resolution:—

"That an opinion be obtained as to the limits within which the investigation or study of the diseases of animals can be legally carried on by means of the funds of the Brown Institution, or otherwise, in the buildings of the Brown Institution or one of them."

Seasonable Benevolence.

On Saturday a sum of £1,500, which had been collected at the different ironworks, factories, and other places of business in Wolverhampton and neighbourhood, was presented to the governors of the South Staffordshire Hospital, as a Christmas box, towards the expense that has been recently incurred in the extension of that institution by the erection of a fever hospital and two new fever wards. This is in addition to £500 contributed by the working men for the object in the early part of the year, and it is anticipated that a further sum of £200 has yet to come. This is but an instance of what the poor can do, if they will only exert themselves on behalf of charities which are established and maintained almost exclusively for their benefit. We commend this action of the working classes of Wolverhampton to the attention of those of large towns generally as well worthy of imitation.

M. Littre, has conpleted his great dictionary of the French language.

If the public is not better protected elsewhere than in Salford from the traders in diseased or decomposed meat, the law for that purpose would appear to be of little avail. The Annual Report of the Public Health Committee of that Borough shows us that for 202 seizures of bad meat made, only seven persons were prosecuted, and only five convicted. Although bad mutton was detected in 110 instances, only one person was punished, and he by a fine of only 10s.; while out of three cases of seizure of bad fruit one conviction was had, and the culprit was mulcted in £10. The five persons punished represent twelve tons of bad meat actually detected, and probably fifty times that quantity which escaped observation.

Medical Practitioners in London who are sensible of the depreciating effect on professional services arising from the action of the numerous gratuitous Medical Institutions are invited by an advertisement to attend a meeting to devise what means of redress are in their power. None but general practitioners are invited. The meeting will be held at 7 p.m., at the London Tavern, on Jan. 9th.

It is hardly necessary to say that there is no truth in the statement in the *British Medical Journal* of the 21st ult., to the effect that Dr. Apjohn, Professor of Chemistry in the University of Dublin, has been appointed Præseotor of Chemistry in Caius College, Cambridge. The gentleman who has been selected for this position is Dr. Apjohn's second son.

The Annual Meeting of the British Medical Association for 1873 will be held in August in London, under the Presidency of Sir William Fergusson. The address in Medicine will be delivered by Edmund A. Parkes, M.D., Professor of Hygiene in the Netley School. The address in Surgery by Mr. Erichsen; and that in Physiology by Dr. Burdon Sanderson. The Hastings Gold Medal, value twenty guineas, will be awarded for the best essay on the "Pathology and Treatment of Ovarian Disease.

The rainfall of the past year is quite unparalleled if the report of a single locality can be accepted as a guide. The greatest quantity of rain which fell for the last five years was in 1869. Other years varied between 30 and 31 inches, or about 2½ inches per month. Up to the end of September last, the rainfall for 1873 was 38·142 inches, or as much as 4·238 inches per month. Since then the downpour has been almost incessant, and the total must by this time have reached an unprecedented amount.

Unlike the fire in Chicago, which destroyed the houses and the personal property of Medical men in common with others, the conflagration at Boston was confined to the business portions of the city, and one only of the Medical practitioners has been driven from his home. The flames which destroyed the offices of the *Evening Transcript*, the *Saturday Gazette*, and the *Boston Pilot*, were arrested within a comparatively short distance of that of the *Boston Medical and Surgical Journal*, which is, therefore, able to continue publication. We congratulate our contemporary on its good fortune.

At a late meeting of the Medico-Chirurgical Society of Montreal, Dr. George W. Ross read a paper on Thoracic Aneurism. The patient had always enjoyed good health, till the spring of 1872. At one time, he had been intemperate. Never had had syphilis. Presented himself to Dr. Ross, on the 12th of last July, complaining of pain, which he said had began to attract notice about three months previously. It was described as being at times burning in character, while at others it was lancinating, getting much worse towards night, at times becoming agonizing, and preventing sleep. Resonance of the chest wall was clear throughout. Heart's sounds quite natural. No murmur to be heard either in front or behind. Striking the vertebræ gave no pain, and a diagnosis of intercostal neuralgia was made. A liniment of soap, opium and chloroform as well as fly blisters were used, and in about six weeks the patient had improved so completely, that he proposed to resume his work of a farm labourer. On the 3rd of September, the pain having returned, he was admitted into the Montreal General Hospital, and on the 15th of October, suddenly expired. A *post-mortem* revealed an aneurism of the thoracic aorta, with a firm clot in the sac of the size of a goose egg, and eroisn of three of the dorsal vertebræ.

AN INQUIRY INTO THE THEORY AND PRACTICE OF ANTISEPTIC SURGERY (*a*).

In this interesting *brochure* Dr. Cumming has put forward the germ theory of disease, and agues with much force and ingenuity in favour of the antiseptic treatment by carbolic acid, as being the most common-sense as well demonstrably true one. Not so much by "excluding air" as has been supposed by some to be the essence of the treatment but "admitting air" which has been purified or deprived of its germs by contact and filtration through carbolised solutions.

He briefly reviews the biogenesis theories of Ridi, or as Schwann expressed it "that something was derived from the air which caused putrefaction." The experiments of Helmholtz, Pasteur, and others, are adduced as proving that not only by contact with an antiseptic material but by a simple porous one can germs be excluded.

The writer himself performed a number of direct experiments in confirmation of the influence of antiseptics on germs in the atmosphere as bearing on the important point in practice, that an antiseptic atmosphere is a sufficient condition to exist around a wound.

His inquiry into the varieties of those organisms, bespeaks much pains and research. He describes—1st. Living organisms; and 2nd. Fungi; and divides these into germs characterised by the figure' motion, &c., of the particles. The author concludes—

1. That air at all times contains organised products capable of giving rise to fermentation and putrefaction.
2. That air can be filtered of these.
3. That air can also be purified by acting on them directly by an antiseptic.
4. That carbolic acid destroys these organisms effectually.

The author, it is hardly necessary to remark, is a devoted advocate of the antiseptic treatment by carbolised solutions, and is specially favourable to the carbolised gauze, and the carbolised atmosphere which can be applied to a stump after amputation by confining the carbolised vapour, without contact.

We can commend this work to our readers as worthy of consideration; it is exact, and from being based on direct observation carries with it conviction.

ON PRELIMINARY CLINICAL INQUIRY (*b*).

In a pamphlet on this subject, Dr. Griffiths, advocates the establishment of a "clinical demonstrator" attached to hospitals who would have no "part in the treatment or care of hospital patients," or, in other words, of a "clinical coach." We can hardly agree that a man could be even a good "coach," who had no means of increasing his store and experience; much less one who would expressly have no part in so doing. We believe that experience and observation, which alone can be obtained by time, will prove the best and most serviceable "coach." If test examinations were properly conducted, and carried out on a broader and more searching scale than at present, the student should apply himself earlier more zealously, and more independently.

DR. THAON ON TUBERCULOSIS.

(Translated by Dr. C. R. Drysdale, Physician to the North London Hospital for Consumption.)

All who have read the works of Niemeyer, and other German histologists, must know how confused are at present the ideas entertained by most physicians, as to the nature of tuberculosis. A further appeal to Nature is required; and the following notes from a series of papers by Dr. Thaon, of Paris, seem to the writer to be of much value. (*Mouvement Medical*, 30th Nov., 1872).

Virchow, Remhardt, and others, have agreed that there are in the lungs of the phthisical only two kinds of lesions, 1. Small tumours, constituted by nodules, isolated or grouped together. 2. Inflammations, under the form of infiltrations (gelatinous, grey, or yellow), limited to one part of a lobe, or extended to the whole of a lobe. This is according to most persons, the whole of tuberculosis of the lungs. Dr. Thaon affirms that the infiltrations of the lung are not only degenerated inflammations, but that they may also be confluent granulations. He affirms this from the observation of 250 autopsies made at the Hôp. des Enfans, and Lariboisière, of Paris. The histological researches were carried out at the laboratory of the Collége de France.

Granular infiltration of the lung, may attack the tenth, the fourth, or the third of a lobe, a whole lobe, or even a whole lung. Dr. Thaon found it to occupy a notable extent in 8 per cent. of the cases in adults, and only 2 per cent. in children. At one time this is seen in chronic phthisis, and takes place in the lower lobes, when it is secondary. At another time it appears suddenly in the upper lobes, whence it descends rapidly as far as the base; that is to say, that granular infiltration may only be the last term of a phthisis of long duration, or, again, may constitute of itself all the disease and the danger of the disease. These facts were presented to the Society of Bilology, on the 23rd November, 1872.

One lung attacked by granular infiltration presented a heavy mass, which sank to the bottom of the water, although this mass was not so heavy as it would be if attacked with fibrinous pneumonia. The external surface, except where [there was tubercular pleurisy, was normal, with exception of some whitish nodules, seen through the visceral pleura. When cut no liquid exuded, and the appearance of the surface of section varied with the age of the lesions. When recent, the infiltration was quite gelatinous and transparent, slightly rosy in hue; later some circumscribed points are remarked, rounded and whitish; these little points form groups, they become opaque and finally yellowish. The number of the groups augments; they press against each other and become extremely confluent. Lastly, we notice grey masses passing into the yellowish condition; but even whilst in this condition, the yellow surfaces preserve their appearance of large grains, and have not the smooth appearance of habitual caseous pneumonia. When the degeneration takes place cavities form. Then different lesions may be met with, united in the same subject, when the progress of the disease is rather slow; but we meet with lungs which are still gelatinous from top to bottom, with rather rare groups of yellow points.

The true differential characters between cheesy pneumonia and granular infiltration, are furnished by microscopic analysis. After having hardened the lung in picric acid,

---

(*a*) "An Inquiry into the Theory and Practice of Antiseptic Surgery." By James Cumming, M.D., M.R.C.P.E., &c., late Resident Surgeon, Royal Infirmary, Edinburgh.

(*a*) "On Preliminary Clinical Inquiry." By W. Handsel Griffiths, Ph.D., L.R.C.P., &c.

gum, or alcohol, we may make very thin and wide sections, which are to be coloured by the picro-carminate of ammonia, and mounted in glycerine. What renders the study of pulmonary tuberculosis very confused is the great variety of lesions in such a complex organ; but we owe also a great number of errors to the insufficient preparations made use of. We must no longer speak of the method of dessication too long employed; alcohol and chromic acid are excellent, but the first does not fix the elements sufficiently, and the second makes them like bladders and gives a network in all directions. Wherever there exists gelatinous infiltration, we find the alveoli filled with little cells (old cytobasts) coloured and closely aggregated. On the walls of the alveoli the capillaries are seen full of blood. A small number of alveoli are quite normal; these were obliterated during life, whence a less tension of the lung than that found in pneumonia. Other alveoli equally few in number, are filled with epithelial elements, swollen, and with a glue-like material.

At this period we may say that the granulation is organised in the alveoli, it arises by buds at the expense of the epithelium of the lungs. This is, besides, the common way in which all tumours of the lungs are developed; lymphadenoma, carcinoma, sarcoma. It has required nothing less than preconceived ideas as to the connective origin of tubercle, to make all the world declare that the granulation in the lung arose exclusively in the periphery of the vessels or bronchi; and it has required very bad preparations not to show its intra-alveolar development. Besides, the fact has, perhaps, been seen but interpreted in favour of caseous pneumonia, even because of its seat in the alveoli; this is to hold the other characters of the neoplasm too cheap.

Thus the granulation exists already in the gelatinous tissue; of the vessels, some are obliterated by end-arteritis, and others by thrombosis. There occur coagulations and heaps of white globules; the whole vessel cut across gives elegant figures, represented by a granular centre of yellowish hue and a beautiful collar of round cells, coloured in a lively way by picro-carminate of ammonia. Circulation is suspended everywhere gradually, the elements crowd together, but are no longer coloured. We have to do with a focus which contains a mass of granules with alveolar walls which are being destroyed, and with fat globules. Both granulations and cheesy pneumonia end then in ulceration, what is characteristic, and separates them are the first steps of their evolution.

What now is the clinical progress of this peculiar form of infiltration? Two are seen. Either the lesion is secondary, it takes place on the last period of phthisis with chronic progress; and in such case it generally passes unnoticed. Or it shows itself at once in healthy individuals, and is primitive. In this latter case, it has a very defined progress; and presents symptoms easily appreciable, but not at all characteristic. The commencement is sudden and accompanied by shivering. We find on listening a blowing sound, with subcrepitant *râles* at one point of the lung, generally at the apex, with dulness on percussion. This dulness and the blowing sound descend, and the whole organ may be attacked, whilst the other lung is attacked in its turn. The patients present a typhoid aspect; the temperature is very high in the morning and evening, 39° 5 C., 40°, 41°; and death comes in about a fortnight. The disease may last a month, or six weeks; and cavities may occur, and the fever is remittent with exacerbations in the evening.

EXCISION OF JOINTS ON THE FIELD.

A Lecture delivered before the Surgical Society of Vienna on 29th May, 1872; from the notes of Dr. C. Fieber.

(Translated from the *Feldartz* by ASSISTANT-SURGEON MACROBIM, Rifle Brigade.)

(Continued from page 182, Vol. XIV.)

OF the greatest importance for the success of this class of operations is the selection of a suitable incision of the soft parts. On the great authority of Langenbeck vertical incisions have been almost exclusively practised, though, however, quite recently a partial reaction against their universal employment has taken place.

The practice is only the revival of an old one followed in the last century by Park, who commenced the first known operation for excision of the knee-joint by a vertical incision over the patella, though obliged, as might be supposed, to supplement this incision by a horizontal one. Again, in the wrist-joint Roux and others, in the beginning of this century, likewise recommended vertical incisions.

What chiefly has led to the employment of vertical incisions has been a regard to the future usefulness of the limb by the preservation of the muscles and tendons, for a vertical incision is less likely to injure these structures than any other shaped incision. But in regarding this object one of still more importance has been overlooked, viz., the providing for a free exit to the pus which the vertical incision in certain joints rather hinders than aids.

In the wrist and ankle joints, it is true, the vertical incision is strongly prescribed on account of the anatomical grouping of the muscles and tendons, while by it, at the same time, in these particular joints, no hindrance is offered to the exit of pus. The same may be said in a less degree of the elbow and shoulder joints. It is different, however, with the knee and hip joints. After an operation on the knee-joint patient must remain a long time in the lying position; and from this circumstance it is clear enough that the vertical incision allows only of free suppuration from the upper half of resected joint, and in this respect is inferior to anterior horizontal or semicircle incisions. The incision is still more unfavourable in the hip joint, for by reason of the great depth of this joint the pus cannot easily flow through a narrow slit wound such as the vertical incision, but requires a gaping, more flap-shaped incision for its easy exudation.

The best incision is that adopted by Hueter, viz., one which describes a semi-circle having the trochanter for its centre, and which cuts through the muscles obliquely, so as to form an inferior flap. It is true that by such practice in both these joints, the cutting through of muscles and tendons must result, but precisely in these joints is this circumstance of minor significance.

In the knee-joint the great object is to ensure ankylosis, consequently the preservation of the quadriceps muscle is of little importance.

In the hip-joint, again, the danger of retention of pus is so great that the more extensive injury of muscles is more than counterbalanced by the more favourable circumstance as supplied by the flap incision for the flow of pus. On the whole, therefore, I consider that we should do better, in the case of the knee and hip joints, to abandon the vertical incision, for we do not act judiciously in compromising the patient's life for an ulterior and secondary good, as the increased usefulness of the limb must be considered to be.

The value of Langenbeck's sub-periosteal incision is, however, of indisputable value.

In cases of injuries of the upper extremities it has been of the greatest use, and more especially in those cases where the shattering of the bone is extensive, and where previously amputation would have been practised. But of the greatest importance of all becomes this discovery in the resection of those joints where the tendons and sheaths of tendons are in close proximity, as exemplified in the ankle, and still more so in the wrist joint. In these joints has the method the great recommendation that the retained periosteum serves as a barrier between the suppurating cavity of the resected joint and the sheaths of the tendons, so accessible as they are to the grafting of inflammation and resulting suppuration; and the preservation of these structures is so necessary that the most complete success of the operation goes for little if the sloughing of the tendons has taken place, for a hand which has a moveable joint, but where the tendons are gone, is much less useful than one where the joint is ankylosed, but where the tendons remain intact, because in the latter case the movements of the fingers still remain.

On glancing at the result of resection with regard to the future usefulness of the limb, it is necessary only to draw a parallel between this result and that of the expectant treatment. Provided the cases for resection are carefully selected, the result is more encouraging than that of the expectant treatment. For while the result, when the bones are injured, of the latter is almost invariably ankylosis of the joint, resection secures for the joints of the upper extremity moderate movements, and therefore an increased usefulness. In the lower extremities much movement is to be considered a misfortune, which only a special supporting apparatus can compensate.

In conclusion, it may be laid down as a broad principle that moderate movement is the best result in the upper, ankylosis in the under; also that a too limited degree of movement, or even ankylosis of the upper extremity, is more desirable than a too extensive movement, viz., where the joint wabbles, and where there is no precision in the motions of the joint. Fortunately, this last result seldom occurs if no more bone that what is absolutely necessary is removed, and if the periosteum be carefully preserved.

SYPHILITIC IRITIS.

(Translated for Medical Press and Circular by Dr. C. R. Drysdale.)

Dr. H. Schmidt (*Berliner Klin. Woch.*, 1872, Nos. 23 and 24), supported by 34 cases observed in hospital, gives this affection a renewed study. In the 34 cases, 1 eye alone was affected in 18; of these, 13 times it was the right eye. There were complications in 31 cases. The great number of complicated cases is far too high to allow us to entertain the opinion that specific iritis is comparatively not dangerous. The writer further remarks that in 24 out of the 34 cases the iritis appeared in the secondary period. Almost all of the cases showed great plasticity; adhesions with the capsule of the lens, exudations into the pupillary region, or hypopion, are remarkably rare. As to Beer's opinion, that the dragging of the pupil taking place inwards and upwards is characteristic of this form, this has not been verified by the author. Pain was generally very severe and widely extended. The loss of vision is generally rather slight; but if notable, we may count on complications, of which the writer gives instances. Condylomata are not rarely seen upon the iris; but these never melt into pus. In very rare forms these gummata also adhere to the ciliary body and the choroid, and may pierce the sclerotic, as Desmarres, Lebender, Arlt, Mackenzie, V. Hippel, Coccius, and the author have observed. In the last-mentioned case—contrary to what has occurred in others named—good vision was retained. We are earnestly cautioned against incision into such a swelling, from the results of the above-mentioned cases.

Another case is mentioned by the author, which was complicated with erysipelas of the face, and where the disappearance of the affection coincided with the commencement of the erysipelas. The author draws the further conclusion from many cases that condyloma of the iris does not occur in non-syphilitic iritis, whereas Desmarres, Arlt, and Mooren say the contrary. Thus, condylomatous iritis is always the expression of constitutional syphilis. With regard to the consequences of this affection, irido-choroiditis only twice was present, and we may therefore say that about 50 per cent. of the patients after iritis possess less than half the power of vision.

As to treatment, mercury was used as general treatment in the form of sublimate or iodide internally; but frequently inunction and subcutaneous injection by Lewin's method in the dorsal region, when no abscesses occurred. The daily dose was about one centigramme. The appearances often quickly disappeared, but often relapsed quickly when the treatment was abandoned. The patients remained, as long as there was pain and the injections were being made, in their room and in bed, and on an average were under treatment from three to five weeks. A solution of five centigrammes atropiæ sulph. to ten grammes (three grains to the ounce) was dropped in twice daily, and small cataplasms used when pain was severe. Leeches on the temples were used when feelings of pressure were felt, and morphia to give sleep. The average time of treatment was from five to six weeks. If the syphilitic iritis withstood all remedies, the author saw good results from repeated paracentesis, in very rare cases, however.

Gleanings.

(From the *Michigan Medical Journal.*)

Dr. de Camp states that in cases of the sickness of pregnancy he never fails to give relief with either oxalate of cerium, calomel, or arsenic. Where bile is vomited and the tongue brown or yellowish he gives calomel. If there be acidity with distress after eating, cerium is the remedy. Where there is loathing of taste, smell, or thought of food, and where there is profuse flow of saliva, there arsenic in small doses is invaluable.

Dr. Broadman, of the Ramsay Co. Med. Society, Minn., mentions a case of typhoid malarial fever, in which, during the worst stage of depression, the subcutaneous injection of 1-48th gr. of strychnia every three hours, had the happiest effect. Dr. Hand, of same place, reports highly of small doses of strychnia with phosphoric acid in minute doses, and gives the following prescription:—

℞ Strychniæ, gr. ss.;
Acidi phosphoric, ʒ ij.;
Syrupi limonis, ad. ℥ iv.;
♏ Coch$^{l.}$ j. min., 3^{tia} vel. 4ta 99hora.

(From the *Detroit Review of Medicine.*)

Dr. Southwood, Ioledo, Ohio, gives a very interesting case of what he terms correctly *neuro-dermic hyperæmia of the hands*, caused by *vaso-motor paresis*. J. N., æt. 23, dry goods clerk, applied for relief for his *bloody red hands*, April 9, 1872. The colour was annoying, and in winter the hands became cold and painful, yet covered with cold clammy perspiration; when pressed the colour receded, and on elevating the hands faded. When he went near a fire he should keep his hands behind him, as heat caused them to itch and burn. After regulating the digestive organs with aperients and quinine, he was given four drops of Fowler's solution, and one thirteeth of a grain of strychnia three times a day, being desired to intermit the use one week in every four. In three months and a half he was quite cured.

Dr. Yandell, in the *American Practitioner*, calls attention to bromide of quinine as a most valuable therapeutic agent in all the sequelæ of syphilis. Dr. Flint, in the same journal, points out that much attention is paid to the effects of over-mental exertion; but that deficient exercise of the intellectual functions, or insufficient activity of the mind is also a great source of morbific agencies, and shows the danger of giving up too suddenly and entirely mental occupation, in which one has been long exercised.

(From the *Philadelphia Medical Times.*)

Opium Poisoning.—The patient took 1¼ ozs. of laudanum. 1-16th gr. of atropine subcutaneously injected dilated pupil, but could not be said to have produced any other evident effect. Constant artificial respiration for three hours, with magnetic electricity, brought the patient through with great difficulty. The magneto-electric and Faradic currents were found more useful for being intermitted and alternative. Benefit was also noted from shifting one pole from over the phrenic nerve to the spinal column.

(*Canada Medical and Surgical Journal.*)

This is a well got-up periodical, and creditable to the Dominion. There are several articles on the outbreak of spinal meningitis of great interest. In the "Hospital Reports" we have cases of idiopathic tetanus, syphilitic ecthyma cured by large doses of iodide of potassium. Severe punctured wound from a bowie knife, separating the coccyx from the sacrum. Amyloid degeneration of kidney and albuminuria. A sound editorial article on sewage ventilation, with several other items of interest. We wish the Editor success, and heartily say, "Floreat Canada."

Correspondence.

THE REPRESENTATION OF THE IRISH COLLEGE OF SURGEONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The Fellows of the Royal College of Surgeons in Ireland may, I think, be thankful that they have in the MEDICAL PRESS AND CIRCULAR a guardian which has evinced an anxious interest in the College, and a fearless vigilance, which the Council to whom such matters have been confided might advantageously emulate. The apathy and (I must add) the pusillanimity which the Members of Council have manifested when so great interests were at stake, and so gross a scandal as Mr. Hargrave's continuance of office existed, ought to be remembered by each and every Fellow when the proper time arrives. If I am rightly informed, it is nearly a year ago since a gentleman, who has since resigned his membership of the Council, brought a blush to the cheeks of his colleagues by courageously protesting against the "over-holding possession" by the Representative of the College; but, although I venture to say every single member then felt and now feels the truth, justice, and necessity of the views then urged, not one of the twenty-one councillors has cared to take upon himself the distasteful duty which he could not but feel devolved upon him. It has, therefore, remained for you, Sir, to put the issue in such a form that it can no longer be disregarded either by the Council, the College, or the Medical Council, and you have certainly left no chink in your argument through which the most easy-consciensed or timid could creep. I write, now, to remind the Fellows that it may probably fall upon them to act in the matter, and, in the most earnest words, to conjure them to estimate the urgency of the occasion, and make themselves heard decisively, if it shall appear that the Council is still unequal to the emergency. It seems to me that the executive body of the College has a plain course before it. Whether your exposition of the illegality of Mr. Hargrave's election be correct or not, it is its duty to express by resolution, as tenderly as may be desired, but in the most unmistakeable terms, its opinion that Mr. Hargrave is no longer capable of doing justice to the Collegiate interests, and that the advantage of the College demands his retirement. That such a proposition is true, and that the members of Council know it to be so is beyond question—that the critical position of the College in regard to Medical legislation justifies immediate and peremptory action is equally undeniable. I cannot believe that, in the face of such a declaration on the part of the Council, Mr. Hargrave would hesitate to tender his resignation; but, should he still persist in his immoveability, it would then be clearly the duty of the Council to take the opinion of its law advisers as to the legal points which you have raised. If its members are still reticent, I certainly think that the occasion is one which requires the intervention of the College, and I should willingly join in a requisition of twelve Fellows (as provided by the Charter) to call an assembly of the College to consider the subject.

The object of this letter, therefore, is to prepare the Fellows for such action, and to show them that neither hesitation nor delay are compatible with the well-being of the College. Are the Fellows aware that not long ago the College was saved from imminent annihilation by the efforts of a deputation, which was, at a heavy expense, sent to London as a nurse to Mr. Hargrave, and then succeeded in defeating a Government Bill which would have put the College under the foot of the Universities? Are the Fellows aware that a resuscitation of the same Bill is in active contemplation, and that probably within a month the Medical Council will meet perhaps to settle its provisions? Are the Fellows conscious that, in Mr. Hargrave's present state, the best thing that could happen would be that he should forego being present, and that judgment should go by default? If they justly estimate these facts I am sure they will not hesitate, should occasion require, to take the matter into their own hands, and I have every confidence that, if the necessity arises, you, Sir, will not flinch from advising them to do so.—Yours, &c.,

A FELLOW OF FOURTEEN YEARS' STANDING.

[We shall certainly not draw back from any course that may be necessary to protect the College from the results of mal-representation, or no-representation, or from the present danger which our correspondent does not, in the least, overestimate. We have every reason to hope that the Council will not leave it to the College to express its opinion on the subject. If the subject were to come before the College the discussion could not be confined to Mr. Hargrave's position.—ED. M. P. & C.]

Medical News.

Longevity of Physicians and Surgeons.—During the year now closing the following eminent members of the Medical Profession have died at the ages indicated, viz.:—Augustus B. Granville, M.D. Paris, F.R.S., senior member of the Royal College of Physicians, 89; Robert Wade, F.R.C.S. England, 80; Thomas Leigh Blundell, M.D. Glasgow, 84; Hugh Agnew, M.D. Edinburgh, 94; Thomas Barnes, M.D. and F.R.S. Edinburgh, 80; Robert Venables, M.A., M.D. Oxon, 88; James Alexander Gordon, M.D., F.R.S., F.R.C.P., 80; Thomas Coleman, F.R.C.S. England, 81; Sir Andrew Smith, K.C.B., M.D. Edinburgh, F.R.S., late Director General Medical Department of the Army, 77; Frederick Carpenter Skey, C.B., F.R.S., late President of the Royal College of Surgeons of England, 73; Robert Wight, M.D. Edinburgh, F.R.S., F.L.S., 78; Edward Thomas Beatty, M.D. Edinburgh, late President of the Royal College of Surgeons and King and Queen's College of Physicians, Ireland, 75; Bowyer Vaux, Senior Fellow of the Royal College of Surgeons, England, 91; James Heygate, M.D. Edinburgh, F.R.S., J.P., 73; Samuel Jeyes, M.D. Edinburgh, 78; William Bodington, F.R.C.S. England, 82; John Gardner, F.R.C.S., 82; P. Miller, M.D. and F.R.S. Edinburgh, 94; Henry B. Leeson, M.D. Oxon, F.R.S., F.R.C.P., 73; Hugh Carmichael, M.A., F.R.C.S. Ireland, 79; William Gibney, M.D. Edinburgh, 78; and Robert Buchanan, M.D. Glasgow, 86.

Singular Cause of Death.—The *Standard* reports on Friday, an inquest was held at Leamington, which revealed a singular cause of an infant's death. The deceased, who was found dead in bed on Thursday, was the daughter of a Mr. Harris, grocer, Victoria Terrace. A *post-mortem* examination showed that death was due to the presence in the stomach of a compact and hard ball of cheesy matter nearly the size of a man's fist. Two Medical men gave it as their opinion that the ball had been accumulating for some time, and was caused by the milk having become changed to cheese in the stomach. Verdict—Natural Causes.

List of Entries in the Register of the Branch Medical Council, Ireland, for the month of November, 1872.

Nov. 1st.—Bond, John, Victoria Villa, Rathgar, Co. Dublin, Lic. R. Coll. Surg. Irel., 1868.

4th.—Kennedy, Thomas Augustus, Cavan, Lic. R. Coll. Surg. Irel., 1870, Lic., 1871, and Lic. Midwfy., 1871, K.Q. Coll. Phys. Irel.

8th.—MacMullen, Hamilton, 62 Upper Leeson Street, Dublin, M.B. Univ. Dub., 1871, Lic. R. Coll. Surg. Irel., 1872.

9th.—Kelly, Peter, Ferry Quay Street, Cork, Lic. R. Coll. Surg. Irel., 1869.

11th.—MacNamara, Patrick Joseph, Knockany-Bruff, Co. Tipperary, M.D. Qu. Univ. Irel., 1872, Lic. R. Coll. Surg. Irel., 1872.

12th.—MacDonald, Denis Peter, Kanturk, Co. Cork, M.D., 1872, and M.Ch., 1872, Qu. Univ. Irel.

15th.—Casey, Philip Forth, The Donahies, Raheny, Co. Dublin, Lic. R. Coll. Surg. Irel., 1872.

15th.—Boxwell, John Henry, Infirmary House, Wexford, Lic. R. Coll. Surg. Irel., 1872.

19th.—Healy, Joseph Keane, Miltown-Malbay, Co. Clare, Lic., 1872, and Lic. Midwfy., 1872, K.Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel., 1872.

19th.—Dill, James Scott, Dromore, Co. Tyrone, M.D., 1872, and M.Ch., 1872, Qu. Univ. Irel.

19th.—Molloy, William, Newry, Co. Down, M.D. Qu. Univ. Irel., 1872.

20th.—Peele, Edward, 19 Adelaide Road, Dublin, Lic., 1872, and Lic. Midwfy., 1872, K.Q. Coll. Phys. Irel.

25th.—Myles, Thomas William, Richmond Hospital, Dublin, Lic. Apoth. Hall Dublin, 1871.

26th.—Fleming, John, Newtown Limavady, Co. Derry, M.D. Univ. Dubl., 1872, Lic. R. Coll. Surg. Edin., 1872.

29th.—Torney, Richard, 20 Ellis's Quay, Dublin, Lic. R. Coll. Surg. Irel., 1864, Lic. R. Coll. Phys. Edin., 1865.

◆

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this request.

All communications intended for insertion must bear the name and address of the writer; not necessarily for publication, but as a voucher of good faith.

Subscriptions in the United States.—A correspondent has drawn our attention to the fact, that some of the houses in the United States are charging the enormous figure of 15 dollars per annum (more than £3) for supplying this Journal to different parts of the States. We beg, therefore, to state that we shall be happy to supply the same regularly, post free, per annum, if paid in advance, for considerably less than half this amount, viz., six and-a-half dollars (about £1 6s. 0d.), either direct from our offices in this country, or through our recognised agents in the United States.

Pass Lists.—In the "News Column" of our last week's journal the names of gentlemen given as having *passed* on the 16th were, by a printer's error, inserted under the heading of the Royal College of Surgeons *instead* of the Royal College of Physicians.

We are obliged to postpone several Original Communications, some of them of great importance.

Surgical Society.—The full report of the discussion on Mr. Morgan's paper will appear in our columns forthwith.

Dr. Proll.—Your letter and the statistics have come to hand.

Dr. Morgan.—The continuation of your article "Peculiar Affections of the Hands and Feet" is in type and will appear in our next. The illustrations have been received.

Dr. B. J. M.—It has been carefully read.

Mr. J. H. N.—You will find the announcement in another column.

A New Remedy for Hydrophobia.—A correspondent requests us to give space to the following, which he has clipped from a German contemporary:—

"A Saxon forester, named Gastell, has made public the means which he has used for fifty years, and wherewith he affirms he has rescued many human beings and cattle from hydrophobia. Take immediately warm vinegar or tepid water, wash the wound clean therewith, and then dry it; then pour upon the wound a few drops of hydrochloric acid, because mineral acids destroy the poison of the saliva, by which the latter is neutralised."

The Adulteration Act of 1872.—The Vestry Clerk of St. Pancras, Middlesex, sends us "a few suggestions on the Adulteration Act," but, as they are intended more for the guidance of the public than of the Medical Inspectors, we can do no more than give space to a short quotation of the duties and fees of the analyst:—

"The Analyst should be required to provide a laboratory at his own expense, and all things necessary for the purposes of analysis. He should be paid by fixed salary, and not be allowed to receive any fees whatever, except fees for attendance in a Court of Justice on proceedings being taken by the Vestry."

To the Editor of the "Medical Press and Circular."

Sir,—I shall feel very much obliged indeed if you will kindly in your *next* issue correct a few clerical errors which appear in the communication I sent you on the 29th November, headed "Aquo Capsulitis," and published in the Medical Press of the 11th inst. The prescription should run thus:—

℞ Hyd. chlor. gr. viij.;
Pulv. opii, gr. j.;
Sach. alb., q. s. m

Divide into *eight* powders. One to be taken three times a-day.

The date following the 16th August, instead of being the 21st July, should be the 21*st August*.

I remain, Sir, yours truly,
J. J. McKeogh.

Thurles, Dec. 14th, 1872.

Medical Society of London.—On Monday evening next the first of the Lettsomian Lectures will be delivered by Mr. Henry Lee, F.R.C.S. Subject: "Urethral Discharges."

Erratum.—At page 10 (inner sheet), of this Number, for Dr. Dowell Stone *read* Dr. Domett Stone.

Communications, &c., have been received from Mr. Cole, C.B., Kensington. Mr. Teevan, London. Dr. J. Cochrane, Edinburgh. Mr. G. Stratten, York. Dr. Stead, Manchester. Mr. Hoblyn, Bath. Mr. Le Neve Foster. Dr. Mitchell, Carlisle. Mr. Green. Dr. Bennett, Cheltenham. Dr. Calvert. Dr. MacCormac, Lambeth. Dr. Goedicke, Romford. Dr. Alexander Lane, Ludlow. The Secretary to the Hospital for Diseases of the Throat. Dr. Neville, Chorley. Dr. Abbott, Brigg. Dr. Henry Land, Exmouth. Dr. Woodward, Worcester. Dr. Daly Moore, Glamorgan. Dr. Langley. Dr. Williams, Westminster. Dr. Morgan, Dublin. Dr. Vance, Rathdrum. Dr. Swanzy, Dublin. Dr. Easby, Darlington. Dr. Reardon, Kildarrery. Dr. Walker, Bonmahon. Dr. Clayton, Athy. Dr. Hely, Carrickmacross. Mr. Fox, Manchester. Dr. Jones, Cork. Mr. Black, London. Dr. Lawlor, Tralee. Dr. Harris, Middleton. Dr. Donovan, Skibbereen. Mr. Backhouse, Leeds. Dr. Franklin, Rush. Dr. Soden, Moville. Dr. Fry, Moate. Dr Waring-Curran, Mansfield. Dr. Sheehan, Buttevant. Dr. Mahoney, Clonmel. Mr. J. Holme Nicholson, Owens College. Dr. Beck, Sawbridgeworth. Dr. Jenner, Hunmanby. Dr. J. Smith, Manchester, &c., &c.

VACANCIES.

Coleraine Union, Portrush Dispensary district. Medical Officer. Salary £70 per annum, exclusive of fees. (See Advt.).

Wallasey Dispensary. House-Surgeon. Salary £100, with residence.

Leamington Provident Dispensary. Dispenser. Salary £70.

Wandsworth District Board of Works. Analyst under the provisions of the Adulterations' Act. Terms to be stated with application.

Metropolitan Free Hospital. Assistant Physician. Honorary.

Manchester Royal Infirmary Dispensary and Lunatic Asylum. Two Assistant-Physicians; two Assistant-Surgeons; one Obstetric Surgeon; Ophthalmic Surgeon, and Dental Surgeon. These appointments are all honorary. Applications must be sent in before the 18th inst.

Parish of Lambeth, Surrey. District Medical Officer for District No. 7. Salary £75, exclusive of fees. Application before the 6th inst.

Chelsea Dispensary, S.W. Honorary Surgeon.

Nottingham General Hospital. Resident Surgeon Apothecary. Salary £150, with board and washing. Applications to be made to the Secretary at the Hospital.

Dental Hospital, London. Dental House-Surgeon. Salary £40 per annum.

◆

APPOINTMENTS.

Dittmar, Mr. W., Assistant Lecturer on Chemistry and Junior Demonstrator in the Chemical Laboratory, Owens College, Manchester.

Hunt, H. J., L.R.C.P.L., M.R.C.S.E., Medical Officer to the West Sussex Prison, Petworth, vice Roger Turner, M.D., resigned.

Mackern, W., M.D., M.R.C.S.E., Medical Officer of Health for the Shardlow Union Rural Sanitary District, Derbyshire.

MacLaughlin, F. P., A.B., M.B., C.M., L.M., Assistant-Surgeon and Registrar to the County Down Infirmary, Downpatrick, vice Hetherington, appointed Assistant Medical Officer to the Downpatrick District Lunatic Asylum.

Payne, G., M.R.C.S.E., House-Surgeon to the South Devon and East Cornwall Hospital, Plymouth, vice Anderson, resigned.

Runcorn, H., M.R.C.S.E., Obstetric Surgeon to St Mary's Hospital, Manchester.

PECULIAR AFFECTIONS OF THE HANDS AND FEET.

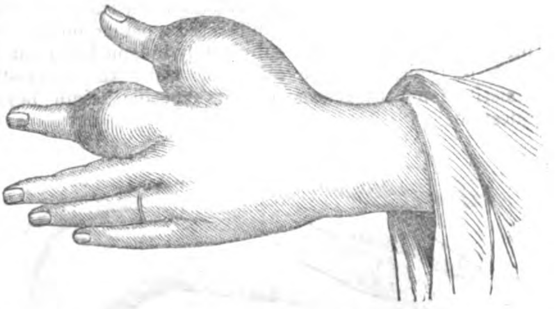
By J. MORGAN, M.D., F.R.C.S.,

Surgeon to Mercer's and to the Westmoreland Hospitals, Professor of Surgical and Descriptive Anatomy, Royal College of Surgeons, Ireland, &c.

(*Continued from Dec. 16th.*)

A VERY typical instance illustrative of a marked form of the milder dactylitis came lately under my notice in a private patient, whose affection presented some peculiarities, and, in whom the previous history was ascertained with accuracy by the gentleman who submitted the case for my opinion.

Her husband admitted that he had infected her some years previously, and both were suffering from unquestionable evidences of constitutional disease; the wife, who was the more robust, was suffering from tertiary ulcerations and pains, together with an exceedingly well-marked dactylitis affecting the thumb and fore-finger, with the milder form of the disease. This condition had existed for some months without causing much uneasiness; the parts could be handled freely, and felt thick and semi-elastic; a peculiar creaking or sub-crepitation could be found at the joints; there was also a leather-creak generally over the swollen parts, the sensation being remarkable, and differing from that of enchondroma or of gouty enlargement, which it most resembles at first sight. The swelling was not abrupt, but gradually merged into the surrounding parts, there was no heat or redness. The illustration shows the remarkable deformity which ensued; yet this condition yielded to specific treatment, and in some weeks had almost disappeared.



A somewhat analogous case is thus given by Dr. Perry in a late number of the *Philadelphia Medical Times*:—

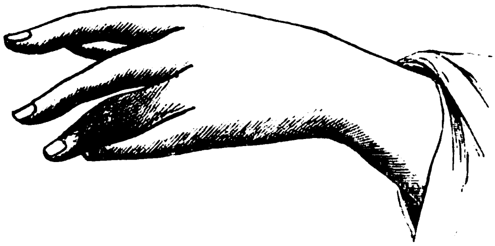
"*May* 29, 1872.—Upon various parts of the body there are the scars of the previous skin-disease. The angles of the mouth are fissured and puckered. On the left cheek is a large rupial crust. The left forearm and back of the hand are covered with the crusts and cicatrices of rupia. The former are from one inch to two inches in diameter. The proximal phalanges of the middle and little fingers of the left hand, and the phalangeal articulation of the former, are much swollen. This is more manifest upon the dorsal than upon the palmar surface, and the former is broader than the latter. The skin over the affected parts is tense, the folds in it are effaced, and the mobility of these fingers is much impaired. The child does not complain of pain in them. They may be firmly pressed or moved without objection on her part. There is no crepitation in the movement of the joints. The outlines of the phalanges are defined with difficulty, owing to the firmness and tenseness of the swelling, but they appear to be slightly thickened, though it is evident that the increase in the size of the fingers is mainly due to disease of the tissues between the skin and the bones. The hand applied to these parts detects no elevation of temperature. The ring finger is much shortened, so that its distal extremity reaches just beyond the proximal phalangeal articulation of the middle finger. It is a quarter of an inch shorter than the little finger. This deformity is due to destruction of the whole of the proximal phalanx. The metacarpal extremity of the middle phalanx has been destroyed, as well as a small part of the distal end of the metacarpal bone itself. In consequence, though she retains but little control over it, the mobility of the member is very great. The nails on all the fingers are perfect and healthy."

In this instance there can be no possible doubt of the specific nature of the disease.

A very interesting case has been under my own observation, which much resembles Dr. Perry's. A boy, æt. 11, suffered from gummatous ulcerations in the following order: on the arm, Nov., 1870; on the nates, Dec., 1870; on the back and shoulder, Jan., 1871; on the chest, March, 1871; and in the fingers and leg in May, 1872. The thumb became affected with a well-marked dactylitis, which suppurated slowly, and comparatively without pain. This boy's sister, who was two years older, had suffered from similar ulcers; and the mother, a person of respectability, admitted that she had been infected by her husband previous to the birth of these two children; the others born previously, and who are still alive, have never showed any evidences of ill health.

As in this instance, a transition may occur from the milder to the more severe form of this affection, which presents more urgent symptoms, and has some features of interest, as it may be, and has been confounded, doubtless, with the more distinctly strumous affections of the fingers, to which, indeed, it is somewhat similar in its course, if not subjected to treatment based on correct diagnosis.

The following is an illustration:—A patient, æt. 23, suffering from nodes on the clavicle and sternum, and also from sore throat, the result of infection by her husband; suffers from a dactylitis of the ring-finger, much resembling that shown in the coloured illustration of Case No. 1. There is a small ulcerated opening on the summit, and the swollen and sub-acutely inflamed state of the skin is typical of the affection, while the co-existing constitutional evidences put its specific origin beyond question.



Ulcerated Dactylitis of Ring-finger.

In this severer form, the symptoms are more active; the swelling is more intense; the skin is so tightly stretched as to be incapable of being pinched up between the finger and thumb; the colour becomes a more or less intense violaceous red, or almost livid hue, and extends over a considerable space; the swelling is very remarkable and tense; there is but little pain; the feel is more of an elastic resistant character than that of fluctuation; and, if a lancet be introduced, instead of the exit of purulent matter, there will be but a thin, viscid, and scanty yellowish fluid exuded, and will much disappoint the expectations of the operator, this is rather a remarkable characteristic of the degeneration of a gummy material; sometimes on passing a probe into the incision a very slight exposure of the bone may be found, as in the following instance under my observation. (*See coloured illustration*).

Case 1.—A boy, nearly three years old, the second child of parents previously healthy, but where subsequently a syphilitic taint was undoubted, showed no evidences till he was two and a half years old. He came under my care suffering from dactylitis of the thumb, which presented all the usual characters of the severer form. There was intense tumefaction; the thumb appeared as if thrust through a ball; the colour was violaceous; there was but little pain. Shortly after the first visit was paid, my diagnosis was confirmed by the occurrence of scattered, but well-marked, papular rash, and the metacarpal bone of the fifth toe became similarly affected; the thumb integument thinned and gave way, and a ragged sinus formed after that the usual thin yellowish fluid had been discharged; a slight roughness could be felt at the bone. A mercurial treatment was had recourse to, which, assuming the affection to have been strumous, would have been contra-indicated; the thumb healed; the rash disappeared; the metacarpal swelling diminished with remarkable celerity; and the child's health became completely robust.

The combination of rash, dactylitis of hand and feet, and cachexia, together with the admitted infection of the parents and the influence of specific treatment, confirmed the accuracy of the diagnosis in this instance.

The following instance is even more interesting, as it points to a confirmation of the disputed question of inheritance from the father alone. (*See coloured illustration.*)

Case 2.—A delicate child of two years was submitted to me in consultation, for dactylitis of both feet. The swelling was tense and violaceous; not very painful, and very obdurate—indeed, its chronicity particularly attracted the attention of the gentleman under whose care the child was, and who had attended the mother in her confinement of this, and of two former children, none of whom had shown any evidence of infection. The father admitted that he had been infected previous to marriage, and he still bore the cicatrices of constitutional ulcers. The case was one of interest and of some doubt. I suggested a specific treatment, which the appearance of a marked rash shortly afterwards confirmed the necessity for. The swelling on one foot became completely resolved, and a small incision made into the other gave exit to thin yellowish matter. It shortly healed, and the child's health became fully restored.

Dr. Perry has also given a case very closely resembling these in history, and where the child had been under observation from the time of its birth.

"*Inherited Syphilis; Dactylitis Syphilitica; Hutchinson's Teeth.*—W. H. H., æt. 10 years, coloured, has been an inmate of the hospital from infancy. Five years ago he suffered severely from nodes on the humerus, ulna, and other parts of the body, with dactylitis, which suppurated after a long period of inactivity, and destroyed the whole of the proximal phalanx of the ring finger on the right hand. The disease is now entirely inactive, but the affected finger is a mere stump, which scarcely reaches the second joint of the little finger."

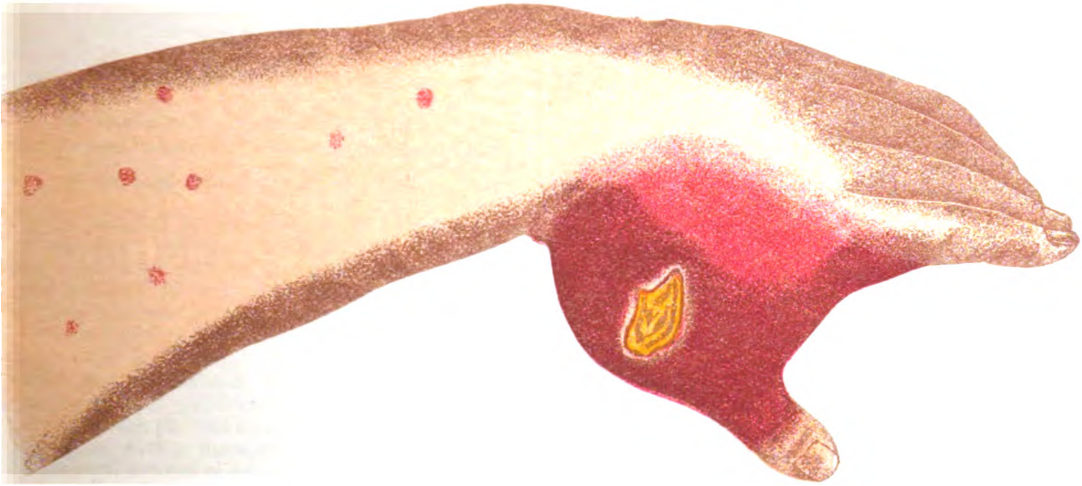
These affections have been chiefly classed as strumous, I am satisfied that in many instances if they be closely examined into, they will be found due to a latent syphilitic taint, and that specific treatment will succeed without surgical interference, or the very extreme measure, of removal of the offending part by amputation or by excision.

The power of reparation under some such circumstances is wonderful, and if early treatment be adopted, much time and consequent drain on the system will be saved. Whether the disease may culminate in a gummatous osteo-myelitis, and destruction of the synovial or articular surfaces may be a matter of speculation in the early stages; I am satisfied, however, that if the disease be recognised, and the previous history of the case scrutinised, a successful termination may usually be counted on, notwithstanding the threatening aspect which may be presented.

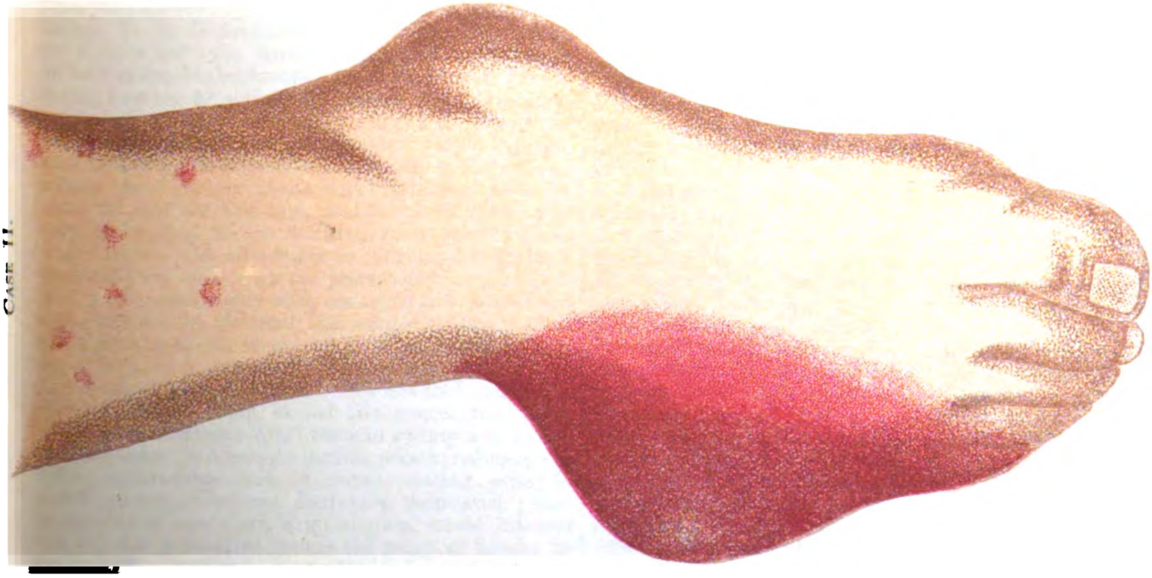
The parts should be kept at rest and warm; gentle pressure should be applied with a bandage, or by strapping, or, what I find very convenient, by painting the parts with one part of tincture of iodine to eight parts of flexible collodion, and specific treatment by inunction, or by the long-established corrosive sublimate and tincture of bark,

PECULIAR AFFECTION OF THE HANDS AND FEET.

Case I.



Case II.



DR. MORGAN'S CASES.

given to such cases under the supposition that they are strumous, should be steadily and carefully employed. Surgical interference by the lancet or knife will be rarely called for. It is needless to remark that the removal of so important an extremity as a finger, without having first had recourse to specific treatment, would be a highly questionable procedure.

MARRIAGE IN THE ARMY.

By Francis R. Hogg, M.D., R.H.A.,

Fellow of the Royal Medical and Chirurgical and Obstetrical Societies.

(Continued from page 432, vol. xiv.)

In India, hospital accommodation for 10 per cent. of full complement of recognised wives, and one half as much in addition for children, is in many stations allowed for cases confined to bed. The dietary for infants is liberal; for children between the ages of 5 and 8 one half, between 8 and 14 two-thirds, above 14 the full diet of adults. On board ship, where those far advanced in pregnancy must not embark, each woman has 15 superficial cubic feet, each child under 10 years of age 7½, and girls above this age the full complement. The wife of an officer provided with a passage can carry 6 cwt. of baggage gratis until arrived at corps or station.

Soldiers.—In 1870 the average strength of troops in the United Kingdom amounted to 82,035; the deaths, 9·48; the invaliding, 37·04 per thousand. It has often been stated that 16,553 men were under 20 years of age; 40,389 under 25; and 52,041 under 30; that Edward the Black Prince held command at the age of 15. Napoleon, Cromwell, and Medical men, prefer maturity, when the bones are perfect. Muscular tenuity, varicose veins, defective vision, flat feet, marks of treatment, heart disease, constituting the main points of recruit rejection. It has been calculated by way of nationality that Englishmen between 20 and 25 give a tractile force of 366 to 384 lbs., the Scotchman from 374 to 404, whilst the Irish range between 399 and 413. Barracks, violently opposed by Londoners, were built in 1739; before this soldiers lived in billets in the beer-houses, livery stables, or lumber rooms of surly landlords. When sickness broke out the surgeon hired a place, sometimes consisting of two small rooms, each 12 feet by 15, for 12 men, with a kitchen attached. To Sir James McGregor the soldier is indebted for a separate bed; the Medical officer also has to thank him for mention in despatches. In old books are records showing how troops suffered in Ireland from dysentery, plague, and malaria, induced by exposure, damp, bad food, and the rascality of contractors. Major Duncan, ever a kind friend to soldiers, and specially to their wives, quotes in the "History of the Royal Artillery" an order dated 1769, that the first man seen drunk or *the least in liquor* be brought to the halberts, there receive three hundred lashes, and afterwards be drummed out with a rope around his neck. In the present day, well-housed, liberally fed, comfortably clad, conveyed in commodious ships, cared for in sickness, the soldier seldom suffers from typhus, typhoid, or scarlet fever, except when contracted from civil population. Dysentery and cholera are in England almost extinct. We are told that if the amount of alcohol taken exceed two ounces, the heart's pulsations are increased 7,000 beats in twenty-four hours, also that tobacco is a vasculo-cardiac poison, reducing the animal temperature, and in excess causing paralysis agitans, vertigo, blindness, dyspepsia, palpitation; that the nicotine of one cigar, if given pure, would kill two men, and that a cannibal prefers the pangs of hunger to lunching off a smoker. Every Medical man knows the ravages of syphilis as wonderfully depicted in Timon of Athens; every tissue is attacked, no organ escapes. How difficult to cure, how rapidly the system becomes poisoned, how easily the sufferer breaks down without the feeblest power of repair; worse than all are the probable consequences to the wife, the almost certain damage to the child, who, escaping scrofula, hydrocephalus, convulsions, or tabes, fatally falls a ready prey to eruptive fevers. This disease is not confined to soldiers. Visit any pathological museum you please, take any town or village of England, in protean shape syphilis will be manifest. Vaccination, railways, as well as the Contagious Diseases Acts, had their opponents, who lived to regret their opinions. Well, the soldier, in addition to the influences of drink, tobacco, and syphilis, suffers from liver, Bright's disease, tropical fevers, and that terrible, subtle, undiscovered poison termed malaria, which science and experience hope to conquer. In 1853 considerable attention was directed to the condition of Plumstead Marshes; sentries on night duty at the Artillery Barracks as well as soldiers' families complained of ague. Dr. John Butler stated that in the months of September and October, 1826, he used daily to visit ninety patients suffering from intermittent fever. Mr. Peter Bossey, who attended the convict hulks, found a difference between 87 and 712 cases of malaria in the ships, *Warrior* and *Justitia*, stationed at Woolwich, owing to anchorage as well as the occupation of prisoners in the marshes. All opinions concurred as to advisability of draining. During the last few years soldiers' families appear to have suffered very lightly. Regarding cholera in India the most recent reports state that Medical science and skill can do nothing secondarily, yet preventive measures in the first instance if feasible might avert the wholesale scourge. Turning to other points, somehow workshops in barracks have scarcely answered expectation. At Woolwich, the soldiers' gardens, each consisting of 1-12th of an acre are let out at sixpence a month, fifteen shillings a year sufficient outlay, the tools and manure provided. At Portsmouth prizes are annually given for flowers and vegetables; and at Peshawur, Sealkote, Mean Meer, and Allahabad the gardens were praised in general orders, but the moving about breaks the interest taken. Respecting barracks many officers are of opinion that the men might sleep in hammocks, and be encouraged to introduce an air of neatness and refinement in their rooms by the addition of neat tables, cupboards, pictures on the walls, indeed, many little things out of the canteen funds. The more men are out of barracks the better. The Roman soldiers, ever on the move, were always healthy and slept well. According to Professor Parkes, each of their tents holding eleven men (allowing 12½ feet per man) were made of skins which, although heavy, were fire as well as waterproof; they also slept on skins.

Foreign Armies.—Let us now consider what takes place abroad, where conscription prevents argument, and the problem is solved how to get good recruits. In France in the Imperial Guard marriage was prohibited; permitted in the Line to about two or three to a regiment of 3,000 strong, the wives acting as vivandières, neither invariably respectable nor comfortably situated. Unmarried soldiers contracting syphilis communicated disease until too ill to drag about. In Spain no marriage under six years' service, even then the woman must have private means. In Sardinia prohibited; in Austria conceded to non-commissioned officers; in Russia encouraged. In Prussia no marriage under three years' service, and to the best of belief in countries where officers or men marry without leave, their children are illegitimate. In the American Regulations there is no information upon this point, nor can any be obtained at present, either from books or individuals. In some newspaper during the graphs found on the dead bodies of French and German late war a contrast was drawn between the various photo- soldiers—the stamp of mistress on the one, that of honest wife on the other. But the French were brave and gallant, and if the reader will turn to Dr. Gordon's most interesting lecture given at Dover it will create astonishment to find such pluck under disadvantages. The pay, about £12 16s. a year, the weight carried on service, about seventy-two pounds, and the allowance of meat, 10½ ounces. Although neither socks, towels, combs, nor razors are included, two pocket-handkerchiefs, drawers, night-cap, and gaiters, figure among the list of necessaries, also two pairs of shoes instead of ammunition boots.

Married Soldiers.—Every man on entering the service subjected to strict Medical examination is considered sound in wind and limb; the diseases afterwards contracted influenced by exposure, climate, vice, or intemperance. Two thousand one hundred and sixty women at various times under treatment were closely questioned about their husbands' health, and the answers tabulated. Those who married twice lost their husbands through phthisis, cardiac affections, Bright's disease, dysentery, cholera, sunstroke, or hepatic ailments. A stated that her husband became paralysed, finally a lunatic; for a long time exposed to tremendous noise, proving guns. B states her husband became suddenly blind whilst undergoing a course of study. C married at 17 a consumptive husband, to whom in Jamaica and Canada she bore five children, who died of convulsions. Next she married another weakly husband, no children resulting. However, the general conclusions arrived at were: Considering everything married soldiers are extremely healthy all the world over when they are fortunate enough to have strong, useful, respectable wives, and in the Artillery we have plenty of them. A dark-complexioned Dorsetshire woman stated that she had six children all alive and well, often nursed two years and a-half; one labour took place on board ship during a storm; she aborted thrice, originally through shock of an earthquake; during pregnancy suffered from obstinate morning sickness invariably with girls, and during lactation menstruated regularly, the climacteric occurring at 45. Had been in Corfu, Malta, Canada, and other places, and was cheerfully packing up to winter at Sheerness. Pressure of other engagements, and preparing to sail for India, interferes with present arrangements, but I trust, when settled down at Meerut, to discuss at length the remaining important professional topics connected with sterility, fertility, labours, fevers, infantile diseases, hospital stoppages, &c., at present in rough original notes. Let me now repeat a former suggestion that soldiers well-recommended should have the first claim, not merely for Government appointments, but also for situations in banks, factories, shops, in short, every branch of civil employ. To soldiers' wives, both of officers and men, feeling indebted for many years' kind appreciation of professional duty, and wishing Woolwich reluctant farewell, allow me to thank the **Medical Press** for the insertion of this paper, also to repeat the words of Sir John Lawrence—"If you wish to *keep* a good soldier make him comfortable at home by treating his wife well."

◆

CASES IN PRACTICE.

Reported by John W. Martin, M.D., M.Ch. Q.U.I.,

Assistant Medical Officer to the Mayfield Factory Dispensary, Portlaw, late Assistant Surgeon to the North Tipperary Light Infantry Militia.

Case III.—*Cardiac Hypertrophy—Valvular Disease—Hæmoptysis and Dropsy.*—Bridget S——y, æt. 18, servant. (Notes taken Sept. 7th, 1871.)

Symptoms.—Constant pain felt in the epigastrium. A troublesome cough, attended with expectoration of blood, since the 1st of September. Dyspnœa and palpitations produced by making the slightest exertion. Stooping brings on an attack of vertigo, accompanied by great venous congestion of the face. The cutaneous vessels of the face enlarged, and filled with venous blood. Great throbbing of the vessels of the neck, a distinct pulsation being present in the jugulars.

Lower extremities œdematous, marked anæmia; tongue lightly furred; anorexia; bowels constipated; states that she passes water freely (subsequent examination proved the absence of albumen or urinary casts). Pulse very weak, unequal and irregular, 100 per minute.

After meals feels oppressed about the heart, is greatly troubled by flatulence.

Physical Examination.—Nothing to be noted about the appearance of the chest, which seemed well formed and well nourished. Eyelids and face œdematous. Heart's impulse strong; the area of impulse enlarged. Cardiac dulness extended, measuring from the lower border of the second rib on the left side close to its articulation with the sternum, four and a-half inches in the vertical direction downwards, and from the right margin of the sternum at the articulation of the fifth rib, over to the left side three and a-half inches in the horizontal position. When the hand is placed over the area of impulse a slight thrill is imparted to it, with each systole of the heart. A loud single murmur heard in its maximum intensity at the point of impulse between the sixth and seventh ribs, commencing before and accompanying the systole, and masking the first sound. A similar murmur to that just described, heard at the right margin of the ensiform cartilage. Loud murmurs are heard at the right and left borders of the sternum in the second intercostal spaces, synchronous with the heart's systole. The second sound very faint. A bruit present in the carotid arteries. Complains of a constant pain in the left shoulder and arm, also in the back. Symptoms of congested lungs well marked.

History.—Previous to her entering upon her fifteenth year she was always a strong healthy girl. About two years and a-half previous to the date of present notes, first felt a severe and permanent pain in the left shoulder and arm, which she described as rheumatic. There was no swelling, redness, or tenderness of the joints at any time. Never had rheumatic or other fever. When young, about twelve years of age, was subject to "growing pains." Since first attacked by the pain described, her illness has steadily gained ground up to the date of presenting herself for treatment. The slightest exertion now produces violent panting and dyspnœa. Her father died of Bright's disease, albuminuria and uræmic poisoning.

Treatment.—A blister 4 × 4 inches applied over the precardial region.

℞ Potass iodide, grs. 50;
Tr. digitalis, ʒij.;
Syrupi, ℥js.;
Aqua ad, ℥xij.

M Two tablespoonsful to be taken three times a day.

℞ Pulv. scamoniæ Co., ℈j., Tales vj.

One to be taken every second night.

Sept. 11th, 1871.—Symptoms much improved; dropsy diminished; cardiac and pulmonary distress greatly relieved.

℞ Liq. ferri perch., ℥jj.;
Tr. digitalis, ʒj.;
Infusi gentianæ, ad ℥viij,

M Two tablespoonsful to be taken three times a-day.

Sept. 28th, 1871.—Dropsy quite gone; general symptoms greatly improved; the cardiac murmurs still retain the characters already described; the respiratory and other distress, at first so prominent in the case, now much diminished. She is able to walk over half a mile without feeling very fatigued, or out of breath. Previous to treatment she was unable to walk fifty yards. Treatment continued.

Subsequent history.—She continued to improve through the months of October and November. In the beginning of December got fresh cold from a wetting. The old symptoms returned in an aggravated form; albumen appeared in the urine; the lower extremities became œdematous, followed by anasarca. In spite of vigorous treatment she rapidly sunk and died.

No *post-mortem* allowed.

Remarks.—From the enlarged area of cardiac dulness and the increased strength of impulse, there was evidently *hypertrophy* of the walls of the heart. From the presence of the bruit heard in its maximum intensity at the point of impulse, replacing the first sound of the heart, and accompanied by a weak, irregular, and unequal pulse, I inferred the presence of *mitral incompetence.* From the presence of a similar bruit, heard over the right margin of the ensiform cartilage, in its greatest intensity, together with the general constitutional symptoms present, there seemed little doubt that *tricuspid incompetence* existed to a marked degree. From the character of the second sound which, although faint, was distinct, from the absence of a "receding" pulse, said to be characteristic of "aortic incompetence," and from there being no murmur accompanying the second sound, I concluded that there was no patency of the semi-lunar valves. From the presence of an obstructive murmur they were probably the seat of warty excrescences to a greater or lesser extent.

The case was an interesting one, from the insidious manner in which the disease developed itself. No history of acute rheumatism or other exhausting disease to account for it. The tendency to the rheumatic dyscrasia, however, existing in the liability to suffer from "growing pains," or as I suppose they should be termed sub-acute muscular rheumatism, so often met with in children at an age, when from the rapid nutritive changes, to which all the tissues are subject, they are peculiarly liable to suffer from influences of an injurious nature. In the case related above the heart seems to have been the primary organ to suffer, the first decided symptom of mischief that presented itself being the pain in the shoulder and arm in the left side, and from the appearance of which the progress of the disease was steady. I believe this pain to have depended upon the condition of the heart, and to have been a symptom of the mischief present which might, had she presented herself earlier to our notice, have been detected, and, perhaps, arrested. Wherever a marked tendency to subacute muscular rheumatism exists I believe the greatest attention should be directed to the condition of the heart, and the subsequent history of the case carefully wstched.

The late development of albuminuria and the absence of "casts" is in favour of the idea that the kidneys were only secondarily affected by the engorgement of the venous system.

DISLOCATIONS OF THE HIP AND SHOULDER JOINTS, ALSO DISLOCATION OF THE PATELLA, AND THEIR REDUCTION UNDER CHLOROFORM.

By Edward Bellis, L.K.Q.C.P.I., and L.R.C.S.I.

In placing before your readers the following cases, I wish it to be understood that it is not with the intention of offering any new feature in their treatment, but simply to record the difficulties experienced in reducing them without the aid of chloroform in country districts, where Medical assistance is not easily procured, and the future welfare of the patient, as well as the reputation of the surgeon, is at stake. I would strongly impress upon all gentlemen similarly circumstanced, not to rely too much on mechanical means no matter how well applied, without the aid of an anæsthetic of some description, and now that the merits of the various kinds are brought so prominently before the Profession, and each in its turn receiving the praise due to it from the operator. I wish to relate my experience in the use of chloroform in reducing the following dislocations, which came under my care in less than three months, in a country practice in connection with Dr. J. F. Little, and the valuable assistance gained by its administration, relieving the agonising pain which the patient is obliged to undergo in such formidable operations, whilst the advantage gained by the surgeon is beyond description, for it must be remembered, that in a country practice, the surgeon whilst operating is so much exposed to the gaze and observations of many ignorant spectators, which in hospital practice is confined to the Profession only.

Dislocation of the Head of the Femur into the Sciatic Notch.—September 27th, I was asked to see John Horan, æt. 29, a strong, muscular man, who met with an accident under the following circumstances, with one leg slightly in advance of the other :—Working in a quarry, a heavy stone slipped suddenly from his hands, falling on his thigh, striking at the junction of the middle and lower third, the opposite thigh acting as a lever, and tilting the head of the bone out of the acetabulum, and lodging it in the sciatic notch, totally disabling him. On examination, I found the leg semi-flexed, and the knee resting on the opposite thigh, the toe on the dorsum of the foot, slight flattening of the buttocks not well-marked ; total loss of power ; shortening of the leg, and great pain. Further examination revealed the nature of the accident. I had before me a formidable dislocation to reduce under great difficulties. With the assistance of some of the quarry men I endeavoured to reduce it, but soon found my efforts were of no avail. I now resolved upon using the pulleys, and being fortunate enough to possess them, I soon put them into use. I made steady and continuous traction for some time regardless of the cries and moans of my patient. This also I had to give up, and seek further advice. At this time, Dr. J. F. Little, who had already been sent for arrived, and at once proposed the use of chloroform, which he undertook to administer himself. Having got him thoroughly under its influence, I again resumed my efforts with the pullies and four strong men. After considerable difficulty I managed to dislodge the head of the bone, and had the gratification of feeling it return into the acetabulum. The extension being made whilst the man was on his back, the thigh flexed on the abdomen, and the leg on the thigh. The man is now at his work as a quarry man, and can walk without the aid of a stick.

Dislocation of the Head of the Femur on the Dorsum of the Ilium.—December 17th, I was called to see Christopher Walsh, æt. 45, working on the railway, who had received an accident under the following circumstances :—He was riding on the outside of a railway waggon down an incline, and shunting from one line to another, in his course he had to pass another waggon standing near the shunting line, and forgetting his position, he was suddenly caught on the hip and sent headlong on the floor, by the collision of his body and the standing waggon. On being taken up he had lost the power of his leg.

On examination, I found the leg two and a-half inches shorter than it should be, and adducted a great prominence over the dorsum ilii ; considerable flattening of the buttocks, and apparent elongation, with swelling and fulness in the inguinal region.

Having satisfied myself of the nature of the accident, I attempted its reduction as before, without the use of chloroform, but the pain and cries of the patient and former experience, soon convinced me that my efforts were of no avail. I now placed my patient under chloroform, and placing a jack-towel well padded round the perineum, and another by a clove hitch knot round the lower part of the thigh above the knee. With the assistance of some bystanders, to whom I had given the necessary directions to make extension and counter-extension, and grasping the thigh, and by manœuvring slightly, was soon able to reduce the dislocation, and had the satisfaction of hearing the bone slipping home into its proper position, in this instance, having no other assistance than a few labouring men.

The chief diagnostic differences in these two formidable dislocations were as follows :—In dislocation into the sciatic notch, the acting force was applied to the distal extremity of the bone. The peculiar semi-flexed condition of the leg, and the jerking movements of the bone in its new situation when rotated, the head of the femur tilting upwards and backwards against the bony boundary of the sciatic notch. The seat of injury did not show much indications of mischief or deformity, and the great difficulty in reducing it.

Deformity in dislocation on the dorsum ilii; the great amount of shortening; the prominence on the dorsum corresponding to the trochanter; the flattening of the buttocks and apparent elongation; the swelling and pain in the inguinal region; the acting force applied to the proximal end of the bone; and lastly, the greater facility in reducing it.

Dislocation of the Humerus into the Axilla.—November 19th, I was asked to see John Kirby, æt. 62, a carter, a strong muscular man, he had fallen off a load of hay, and in his descent, his shoulder came in contact with a wooden pailing. On recovering himself, he found he had lost the use of his arm. I found the elbow sticking out, the arm semi-flexed and held over his chest, and passing my hand over the acromion, I came to a depression corresponding to the head of the bone, and unusual fulness in the axilla. With the assistance of some men, I endeavoured to reduce the deformity, placing a jack-towel round his chest, and another by a clove-hitch knot round the arm. I placed my foot in the axilla, trying now with considerable force to reduce it. I then used my knee in the axilla, and many other movements, but found it useless. At last I had to give it up, and being five miles from home, it being late, I left it till morning; and accompanied by Dr. J. F. Little, by whom he was placed under chloroform, I again attempted the reduction, and was soon able, under the use of chloroform, to accomplish single-handed, what four strong men failed to do without it. The man is now at his usual avocation doing well.

Dislocation of the Patella outwards on the External Condyle.—December 19th, I was called to attend John Pinnington, æt. 28, strong muscular man, he was wrestling with another, and in making strenuous efforts to throw his opponent, his foot slipped, and he fell to the ground, losing the use of his leg, and soon discovered that the cap of his knee was out. His leg was semi-flexed, with the knee flattened and broader than natural, and the patella displaced outwards. I attempted its reduction for some considerable time without the aid of chloroform, but totally failed. I now placed him under the influenee of chloroform, and whilst undergoing it, I discovered his eyes turn up, his face became distorted, the muscles twitching, the hands and arms became contracted to such a degree, that I was alarmed about his safety, and stopped the administration of chloroform. Turning now my attention to his knee, I was agreeably surprised to find that, during this paroxysm, the patella had slipped back into its proper place, and he soon recovered from his unpleasant position, and was able to walk home. This man, though strong, was so deaf he could only be spoken to by signs, and I attribute the unpleasant symptoms caused by chloroform to his deafness, the result of a former injury.

I trust that these practical hints may prove of service to many country practitioners, where Medical aid is not easily obtained, and when such accidents are left unreduced and sent to the nearest hospital, or may be a "bone setter," it exercises such damaging influence upon the practioner's future career, and materially interfere with his future prospects.

Woolton, Liverpool.

Hospital Reports.

MEATH HOSPITAL.

Lithotomy.

Mr. Macnamara last week, in the operating theatre of the Meath Hospital, extracted by the lateral operation, and under the influence of ether, a large sized calculus from the bladder of a boy, æt. 14. The ether was administered by Professor Morgan, who employed the instrument invented by himself for the purpose, and which he has already described in the pages of this journal. Nothing could be more satisfactory than the anæsthesia produced; there was no sickness, no struggling, but there was perfect relaxation and complete insensibility, and the rapidity with which these were produced, may be inferred from the fact that the patient was back again in his ward, relieved of his calculus, within twenty minutes of his having left it.

◆

Transactions of Societies.

THE SURGICAL SOCIETY OF IRELAND.

The Society met on the evening of Friday, the 13th Dec.; the President of the College in the Chair.

The discussion on the question of

THE RELATIVE VALUE OF ETHER AND CHLOROFORM

was resumed by Dr. **Robert McDonnell**, who said that Dr. Morgan had, in his opening statement, touched upon a considerable number of topics of interest; but there was one point mentioned by him on which he (Dr. McDonnell) felt he could speak with a little authority. He alluded to the use of ether in America. As he had just returned from a visit to that country and had seen the actual practice there, he could state what had come under his own observation. There, as here, there was a good deal of difference of opinion on the relative merits of anæsthetics. In Boston ether was used. He had seen it administered most freely in the Massachusetts General Hospital, and admitted that he had been greatly impressed with what he had seen. The freedom and the confidence with which it was used, the recklessness (as we would call it here) with which it was given, spoke volumes for their belief in its safety. The anæsthesia produced was profound; it was delightful to witness at once the absolute unconsciousness of the patient, and the easy confidence of the operator, which contrasts with the very partial and imperfect anæsthesia induced amongst us, and the nervous anxiety of the operating surgeon when chloroform is used. The ether was administered by pouring it on a large sponge, and giving it to the patient with a profuseness which bespoke the most perfect confidence in its safety. There was a rule in the Massachusetts General Hospital that they must give ether, and chloroform was absolutely prohibited. He could not help saying, when he heard this, that if he were connected as surgeon with that hospital he would strongly protest against any such rule being laid down by governors who had no right to prescribe rules for the Medical officers on such a subject (hear, hear). In New York there was considerable difference of opinion. In the Presbyterian Hospital he saw ether administered freely for the removal of the scapula. Dr. Marion Sims said he had been using the nitrous oxide gas even in prolonged operations, such as ovariotomy. In ophthalmic hospitals they sometimes gave chloroform, sometimes ether, perhaps more usually chloroform, as being more rapid, and answering well in young subjects; while in the more debilitated and advanced in years, they preferred ether as being more stimulating. Professor Dalton prefers to administer ether to dogs in his physiological experiments. He saw this distinguished physiologist administer it to a dog when putting a tube into the pancreatic duct. He (Professor Dalton) adopted ether, because he had found he lost so many dogs from the use of chloroform. He (Dr. McDonnell) himself found that it was very fatal to dogs, and if they looked to the physiology of the subject, which is a very important matter, they would find that ether was the safer of the two. Dr. Morgan pointed out that in giving ether vapour there should be as slight an admixture of air as possible. In this point there was something new and interesting. Dr. Morgan had kindly administered ether to three or four patients in Steeven's Hospital with his apparatus, and as Dr. McDonnell thought with very excellent effect, both as regards promptness of action and completeness of anæsthesia. It acted promptly and very satisfactorily. The great points they had to consider were the safety, the facility of respiration, the avoidance of hysteria, and sickness of stomach. It must be admitted they had not before them sufficient data to form a positive conclusion as to these points. It appeared to him that upon this subject they had been in the habit of making rather loose assertions. It was desirable that they should obtain more precise information, and he thought that the Society might do a great deal of good if it were to collect accurate observations made with precision. He meant by tabulating cases in which the exact condition of the patient was taken into account—when the last meal was taken; what was the condition of the stomach; how long anæsthesia was maintained. All these and many other points must be examined into before they could say whether ether or chloroform was the safer or the less apt to cause vomiting. With regard to hysterical excitement the same course must be pursued, and there must be careful observation of a considerable number of cases before any definite conclusion can be arrived at. He recollected when ether was first administered in Dublin in the Richmond Hospital by his father, in a case where an arm was amputated above the elbow-joint. He (Dr. McDonnell) was then a student, and he remembered to have made and noted a considerable number of experiments on himself. The thing that struck him most was, that there was a great difficulty in respiring ether vapour as a strong inspiration brought on spasms of the glottis and coughing; whereas chloroform entered the glottis easily, and produced an agreeable feeling within the chest. As to his own sensations, therefore, chloroform had an advantage over ether as regarded respirability. But what they wanted was a large number of cases, so as to give them the statistics; first, respecting safety to life; and next, respecting sickness.

Dr. Wilson said he had been giving ether exclusively in St. Mark's Hospital for the last four months, and was, therefore, able to speak with some slight experience on the subject. Dr. Joy Jeffries, who lately visited this country, was very enthusiastic in its advocacy, and he had seen him give it with very great effect, the most perfect muscular relaxation having been caused by it. As it had been pointed out to him by several American surgeons that ether was free from danger he used it instead of chloroform; not that he had had a bad experience of chloroform, but every time he gave it he had a dread of its fatal effects. He found that in adults and robust individuals it took a very large quantity of ether to bring them under the influence of narcosis, so as to produce muscular relaxation sufficient for operation, and he had found certain persons difficult to render insensible. In one case he used several ounces of ether, but had to put the individual off the table, being unable to bring him under the perfect influence of the drug. On a subsequent occasion, however, by using a different method he succeeded in perfectly narcosing that individual with ether. Again, he found that to avoid sickness ether must be administered on an empty stomach, as he had only given it in one case where there had been no previous preparation of the patient, in which there had not been sickness of stomach. So far as his experience went the sickness was greater than when chloroform was used. He also found the excitement caused by ether was greater than that produced by chloroform, and when he administered the former he always had a larger number of assistants to control the patient. The time of administration differed in various individuals, from one minute in an infant, to twelve or fifteen minutes in adults. He always administered it with a towel, into which a piece of wool was stuffed, and the quantity of ether used was large. As to whether it was an agreeable anæsthetic or otherwise patients varied. One man told him it was like going down into the depths of the ocean; but he admitted he had had no experience of that fact, and only imagined the sensation must be like it. Ether was far more disagreeable to administer than chloroform, the odour remained in the apartment a long time, it clung about the clothes of the patient, and it remained even on his breath for two days afterwards. To sum up his experience he must confess he preferred the administration of chloroform in every respect, and were it not for his inherent consciousness that chloroform was sometimes fatal, he would never administer ether; but he was driven into his administration of it by his dread of the fatality of chloroform. No doubt chloroform had been given thousands of times in this city, and the fatal results were almost *nil*, but he could not divest his mind of that fatality, infinitesimal though it was.

Dr. Morgan—In how many cases have you given ether?

Dr. Wilson—In about forty; and I have usually given an ounce and a half each time on the towel.

Dr. Jacob said the line of practice in which he had seen ether administered was the same as that in which Dr. Wilson had narrated his experiences. In the first instance he might be supposed to speak with some little authority as to Dr. Morgan's mode of administering ether, for he did not think any surgeon in Dublin had had so much opportunity as he had had of observing its effects. He had the pleasure of assisting Dr. Morgan in his first inception of the plan, and he had followed him through the various steps that had brought him to the perfection of his present inhaler. Dr. Morgan admitted that the administration of ether was open to the objections raised by Dr. Wilson; but Dr. Morgan's reply was, that he had obviated all these objections, and that for the future ether, as administered by his inhaler, had superior claims over chloroform on the attention of surgeons. The effect of the experience he (Dr. Jacob) had had up to the time he gave attention to this matter was, that he altogether discarded the use of anæsthetics in ophthalmic practice. He had very good reasons for doing so, for he thought that chloroform as usually administered had certain drawbacks which made it an undesirable agent in ophthalmic surgery—the sickness of stomach, the great excitement of the patient, the inevitable flurry attending the operation, and lastly, the disorder of the head and stomach afterwards, were reasons which appeared to him to counter-balance any advantage which operator or patient could derive from the use of chloroform. He had very good reason to give attention to this subject, for in the very first case he had to operate upon in private he very nearly lost his patient, although he had the assistance of an eminent surgeon on the occasion. He was unwilling to face such a contingency again, and certainly would not do so for the sake of any insignificant detail. This was, therefore, the reason he had resorted to the use of ether, which he had found to act in the most satisfactory manner. Since the 17th of July last he had operated in thirty-seven cases, exclusive of unimportant ones, in the Dublin Eye and Ear Infirmary, the patients being put under the influence of ether by means of Dr. Morgan's inhaler. Dr. Wilson said that it took a large quantity of ether to produce anæsthesia, that only in one instance was there no sickness, that the excitement was greater than with chloroform, and that it took from one to twelve minutes to produce insensibility. His experience was the exact contrary. In the whole of the thirty-seven cases referred to there was not one case of sickness, with the exception of a boy who disobeyed orders, and took his dinner a few minutes before operation, and the only case since in which he operated under the influence of chloroform was sick. As to the excitement, any body who had observed a series of cases in which ether had been given by Dr. Morgan's inhaler would say the excitement was *nil*. In the majority of cases there was no interval between the first administration of the ether and insensibility, there might be some muttering delirium, but nothing of the least inconvenience to the operator. It appeared to him, however, that all these little details sank into insignificance as compared with the question of safety. No one would run the risk of destroying life if he thought chloroform involved that risk and ether did not. Dr. McDonnell thought that that point had not been established by the statistical tabulation of a large number of cases. He thought, however, from Dr. Morgan's statement, that a sufficiently large number of cases had been established to enable them to form an opinion on the subject. It appeared, from the figures collected by Dr. Richardson, of London, that the mortality from chloroform was eight times greater than from ether, and if those figures could be depended upon they went a long way to persuade the Society that Dr. Morgan and the advocates of ether had not arrived at a hasty conclusion. The cases he (Dr. Jacob) had operated on were the ordinary run of ophthalmic cases. To sum up his experience he would say that, whereas he never ventured to suggest the use of chloroform, he now would never think (unless in future he saw some powerful reason to change his mind) of operation without suggesting the employment of ether, both for his own sake and that of the patient.

Dr. Kidd observed that he regarded the statistics which had been brought forward with very great doubt. Dr. Jacob and others had spoken of ether as if it were absolutely devoid of risk. Now, a very short time after ether was introduced, a death occurred from it during an operation in Edinburgh, before the anæsthetic power of chloroform was discovered; and very soon after Dr. Joy Jeffries returned to America a report of a death from ether reached us from that country. He believed that the inhalation of chloroform had been practised in this city for twenty-five years, and there had not been more than four deaths attributed to chloroform; if there were five it was the very utmost, and he understood that one of those arose from the entrance of air into the veins, and not from the influence of chloroform at all. It was a remarkable fact that Sir James Simpson, who perhaps administered more chloroform than any one else, never met with a fatal case until the last year of his life. In 1870 a patient died during an operation for ovariotomy when Sir James himself administered the chloroform. In publishing that case he adduced a number of cases where death had occurred from shock before any anæsthetic was used. In the first case, in which it was intended to administer chloroform in the Edinburgh Infirmary, Sir James Simpson was sent for to administer it. He happened to be out of the way; the patient was put on the table to be operated upon, and before the first incision was made the man was dead. If Sir James Simpson had happened to be in the way, and administered chloroform on that occasion, we should probably never have heard anything more of the administration of chloroform. He thought Dr. McDonnell's suggestion as to tabulating the cases one of the most important matters which that Society could take up. He thought they had not sufficiently definite and accurate information as to the deaths. To say that in a certain number of cases there had been a certain number of deaths without giving specific details, afforded no means of arriving at a sound conclusion. It was said there was no sickness from ether administered with Dr. Morgan's inhaler. Now, he had recently seen it administered to two patients by that method—in one case administered by Dr. Morgan himself; and in the other by a gentleman represented by him. In one of these cases Dr. Atthill operated in the Adelaide Hospital for vesico-vaginal fistula, and the woman was sick three times. In the other case Dr. S. Johnstone operated in the Military Hospital for vesico-vaginal fistula, and the patient was sick several times, and a good deal more excited than was generally the case when chloroform was administered. In the last number of the *British Medical Journal* a writer, who signed himself "Chloroformist to the Westminster Hospital," stated that he had administered ether during the last year, and that the secondary sickness after it was about the same as that which occurred after chloroform. He thought it a most important thing that they should occasionally review their progress, and not allow the weight of authority even of so great a man as Sir James Simpson, to prevent them examining for themselves what they were doing. He must say, therefore, he was exceedingly glad that this matter should have been raised again, and if he rose to speak in opposition to what seemed to be the voice of the evening, it was not because he had come to a conclusion as to the relative merits of ether or chloroform, but because he thought they should not be carried away by impulse to the setting aside what had hitherto been a good and useful friend, and adopting another instead of it.

Dr. **Atthill** said he had lately brought a patient under the influence of anæsthetics on three occasions, and on each occasion he tried a different anæsthetic at an interval of three weeks between each administration. On the first occasion he gave her chloroform in the ordinary way. She was very sick at the time and sick afterwards. Between that and the next occasion he had read Dr. Morgan's pamphlet, and was very much impressed by it, and had asked him to come down to administer ether to this patient also. He did so, and she was sick in a less marked degree than with chloroform. He asked her which of the two anæsthetics she preferred, and she said she preferred ether. After three weeks more it was necessary to put her under the influence of an anæsthetic again, and on that occasion Mr. Richardson administered a compound of equal portions of chloroform and rectified spirit, and it produced an anæsthesia as well as either of the other agents, and the patient was not sick then or afterwards, and she preferred it to either of the others. All unprejudiced members of the Society must come to the conclusion that neither of the anæsthetics in question was perfectly safe. The question was—Which was the safer of the two? In instituting the comparison between them, they should not forget to bear in mind the combination of chloroform and rectified spirit which had been so successfully applied by Mr. Richardson, acting under the opinion of Dr. Snow, who considered it safe. Probably it was safer than either chloroform or ether, and in the case to which he referred it had acted most satisfactorily.

Dr. **McDowell** could corroborate every word Dr. Morgan stated. He considered ether preferable to chloroform, both on account of its safety, and also because it produced less hysteria and sickness of stomach. He looked upon chloroform as a direct poison to the heart. The patient takes a rapid inspiration, the chloroform was carried to the heart, it entered into the coronary artery, and the patient died. He had seen a hundred cases in which ether was administered, the patients got rapidly under its influence, there was smaller excitement than with chloroform, and he never saw but one case that was followed by sickness of the stomach, and that case occurred in Mercer's Hospital, and the patient was not prepared for the giving of the anæsthetic. Ether acted very rapidly when administered by the inhaler. He had seen it operate in three, four, five, and eight minutes, and he had never seen a case in which it took more than eight minutes to produce insensibility. It was a mistake to think that ether was not permanent in its effect. He saw a patient, both of whose feet were amputated. The operation lasted three quarters of an hour, during the whole of which time there was the most perfect muscular relaxation, and there was no sickness, nor any of that heaviness which followed the administration of chloroform.

Dr. **Rawdon Macnamara** thought that great credit was due to Dr. Morgan for bringing this question before the Society. Since he had taken it in hands the merit of it had been claimed at the other side of the channel, and they should, therefore, feel grateful to Dr. Morgan for vindicating the claims of Irish surgery on this subject. It had been suggested that recourse should be had to statistical records. Now, he had not confidence unbounded in statistics. He had heard a good deal of Ether *v.* Chloroform, and it would seem from the observations they had heard as if there was never such a thing as a death from ether at all; whereas, recently there had been published four cases of death from ether, and if statistics were published they would find that ether could claim its victims as well as chloroform. He was aware there had been deaths from ether, and in the discussion that evening they had been slurred over. He had taught for many years as Professor of *Materia Medica* that there was a great deal more than paralysis of the heart in death from chloroform. He believed that there was such a thing as an idiosyncrasy, and that certain patients would not tolerate the administration of certain drugs which acted upon them as poisons. He had frequently stated to his class that if a man administered chloroform to 2,000 people he would certainly have one death out of that number. He had administered chloroform as often as any person in that room, and he was happy to say that up to last summer he had never had a death. On the last occasion, however, he could not state this. He was administering chloroform to a patient who was being operated on by an able surgeon, when suddenly he said to him, "This woman is dead, Sir." The woman had taken it as quietly as possible, when, like the shot of a gun, she expired. As if we had had a presentiment of what should occur, we had brought a galvanic battery with us, and we spent two hours in trying every means to resuscitate her, but all in vain. He believed that death was due to idiosyncrasy, and not to chloroform. He thought that in order to make perfect the statistics of which they spoke, they should know the number of people who were liable to these, and also ascertain whether, while chloroform would kill such persons, ether would not have the same effect. He had been in the habit of administering chloroform to patients, and they went to sleep as quietly as a child in the nurse's arms. He did not think that ether had, on that ground, any advantage over chloroform. If a man knew how to administer chloroform, and followed the rules he had laid down, he would be able to make the patient pass off slowly, and without a struggle, to insensibility. If chloroform or ther were dashed on a patient's face, of course there would be a struggle. He had lately seen ether administered in an heroic manner: there was a great struggle, and the patient said he would rather suffer from the disease than have to undergo that struggle again. All the authorities said that in administering ether most of the patients must be held down to overcome their violence. He could administer chloroform without any such struggle, and the patient would fall quietly asleep, and without any pain. As to shock, which had been alluded to by Dr. Kidd, there could be no such thing as shock under the influence of chloroform. He believed an enormous number of deaths, attributable to shock, occurred before anæsthetics were brought into operation; but he did not believe any patient under the influence of chloroform or ether was liable to death from shock. It might be important to ascertain what was the state of the atmosphere when chloroform was administered. Again, he came back to the point that statistics, as at present collected, were most unsatisfactory. They were not satisfied with chloroform. Every surgeon was in a state of tremor while administering it, and he said that in administering ether it would be the same. (No.) That "no" must mean that there had been no deaths from ether. If there had been no deaths from it, then the questions of convenience, sickness, &c., sank into insignificance; but if one patient had died from it, the presumption was that other patients would also. No doubt there was a desire to find out some safe anæsthetic. Sir James Simpson said that, while we had made a large advance in the administration of chloroform, yet he considered the desideratum was yet to find—viz., some agent that would be perfectly safe.

Dr. Kidd said that when he spoke of death from shock he did not mean when the patient was under the influence of anæsthesia, but death from shock when no anæsthetic was used. He believed chloroform diminished the risk.

Dr. Henry Kennedy said,—I wish I could look upon this subject from the same point of view as some of the speakers who preceded me. But I must here state, once for all, my strong conviction that anæsthetics, of whatever kind, cannot be used so as to cause insensibility to pain without leading to more or less danger to life. The risk, it is true, may be very very small, but some risk there will always be. My experience of anæsthetics began long before the use even of ether or chloroform; for I was once present at an exhibition in the Rotundo, where part of the performance was to be the use of the laughing gas to any of the audience who pleased to take it. On the first two the effects were simply to put them to sleep, as it were, and after a moment or two they woke up; on the third, the face became very congested, and the vessels of the forehead tense, and then he suddenly burst into what I might call an incoherent laugh, which subsided in a short time; on the fourth the effects were still more marked, for just as his face became conjested, he suddenly rushed from his seat, ran violently round the room, and, coming in contact with a form, on which some eight or ten persons were sitting, upset the whole of them, producing at the same moment both a ludicrous and somewhat alarming scene. Subsequently I saw ether used in this College, and, as some present are aware, the effects were very similar to those of the nitrous oxide, except that in these last direct force was used to restrain them when the persons showed signs of violence. Chloroform, I need scarcely add, produces similar, though somewhat modified effects. With such facts in my mind, I have come to the conclusion that it is not so much the special agent used we should consider, but the human frame, and its state at the time the anæsthetic is used. And this leads me to a most important part of this subject; for, though others may ignore the facts, I cannot forget what has been published by the late Dr. Snow viz., that out of the fifty fatal cases which he has detailed, the vast majority were found to have had fatty heart. Yet, with such a statement before us, the opinion is still held by many that such a state does not or should not influence us in the use of an anæsthetic. For my part I cannot entertain this idea; and here I am led on to observe that it would seem as if more deaths have occurred from chloroform in England than in any other country. Whether this be due to a different constitution of the people I cannot say; but the point is worthy of consideration. As to the care bestowed on each case, previous to the exhibition of the anæsthetic, I cannot but think it might be increased. It is true, it is always stated that the ear being applied to the chest the lungs and heart were found to give the normal sounds, whilst the pulse at the wrist beat steadily. But such a statement as this I have long endeavoured to show is not sufficient; and, in a paper I had the honour of bringing before this Society, some two years since, this very point was strongly urged. And the reason is obvious enough; for, while we have a radial pulse to show us the state of the left heart, and how it is going, we have none in connexion with the right, and, as is well known, this portion of the organ may be seriously [illegible] whilst the left is comparatively healthy. I would, therefore, venture to suggest that in every instance where an [illegible] was about to be used, the Physicians to the Hos[illegible] should closely examine each patient, and report accord[illegible]. By this means I believe danger might often be [illegible], or if the anæsthetic must be used, ten-fold caution [illegible] exercised. One other suggestion and I have done. [illegible] symptoms arise, I think that in addition to the [illegible] used to revive the patient, oxygen gas might be [illegible]. My reason for this arises from a statement I heard made by the late Mr. Cusack, to the effect that when chloroform was given it rendered the blood dark. I know not whether such a suggestion has been made before, but it seems to me one worthy, at least, of a trial.

Dr. Grimshaw wished to call attention to the influence of these two anæsthetics on the heart. There was one point in Dr. Morgan's pamphlet which struck him greatly, namely, the pulse tracings given at the end, which showed most unmistakeably the beneficial influence of ether on the pulse. So far from diminishing the pulse, ether considerably increased it. In one case especially he noticed that it materially improved the state of the pulse. Another point of interest was referred to by Dr. Kennedy, namely, the colour of the blood. In one of the cases operated on at Steevens' Hospital, he noticed that the blood was not altered in its colour under the influence of ether, and he believed this was due to the great amount of oxygen which ether contained. About twelve years ago he administered ether in Steevens' Hospital for one of the surgeons there, who was induced to try it on account of an accident he had met with in the administration of chloroform, and which followed on the second administration of that drug. That was a case of dislocation of the shoulder into the axilla, and the patient was put under the influence of chloroform in order to reduce the dislocation. The attempt, however, failed; the patient recovered, and was perfectly well for some days after, and then another attempt to reduce the dislocation was made. The patient was again put under the influence of chloroform (the person who administered it not being the same as on the first occasion), and he died under its influence. Afterwards he (Dr. Grimshaw) tried ether for the surgeon to whom he referred, and apparently very satisfactorily. He had had some experience in looking into therapeutic statistics, and, as ordinarily collected, he looked upon them as fallacious. The figures quoted by Dr. Morgan, who had taken great trouble, no doubt, to get them accurately, were, as absolute figures, unreliable; but, as far as the proportions were concerned, they were probably fair enough, and he was justified in relying on them in support of his views. He knew of two cases of chloroform deaths that had never been reported, and he thought it likely that the suppression of fatal cases from chloroform and from ether had been in the same proportion.

Dr. Darby said, that upwards of twenty years ago he stated in that room that he did not think all the pain saved by the use of anæsthetics would counterbalance one death from the use of the drug. He was of that opinion still, and there was not a man present that would run the risk of losing his life because of all the pain that might be saved to the rest of mankind by the use of chloroform. Ether had formerly been used in Dublin, and it had been expelled, and chloroform introduced in its place; and the discussion that evening had proved that chloroform was an unsafe drug, justifying the observations he had made twenty years ago. He had been an operating surgeon for many years, and at present had 300 patients under his care; but, although operating every day, he never used chloroform or any anæsthetic, for even if he were disposed to use it, he had no one to assist him. Dr. Darby repeated his opinion as to the danger of administering chloroform, and expressed his belief that more deaths had occurred in the last twenty-five years from chloroform-poisoning than from all other kinds of poisoning put together.

Dr. Fleming said that on the introduction of chloroform as an anæsthetic he brought the subject under the notice of the Society, and he believed he was the first person to call attention to it in this city. He had seen the exhibition of it by Sir James Simpson, happening to be in Edinburgh at the time, and was struck with the excellent results which it produced. As there was so much difference of opinion regarding the relative merits of chloroform and ether, he would suggest the appointment of a committee from the representatives of the several hospitals of Dublin to inquire into the subject, to tabulate accurately all the figures and details connected with it, and bring the matter before the Society at the conclusion of the session, or at such other time as might be fixed upon. They would then have an opportunity of investigating the subject more thoroughly than they could at present, of forming their opinion on the facts produced before them, and they would be less liable to be carried away by partizanship, or a disposition to advocate the opinion of this or that person without due consideration. For himself he must say that he was an advocate for the use of chloroform. In one class of cases it was productive of the most beneficial effects—he meant at an early period of childhood. He had administered it in hundreds of cases to children, and it always acted in the most satisfactory manner; and he had also given it to adults in great numbers, and never had a fatal case. He had administered chloroform in cases of strangulated hernia where the patients were in the utmost state of prostration with sinking pulse, and yet nothing could have been more satisfactory. In other cases of affections of the chest, where the heart was involved—aye, even in such cases as those alluded to by Dr. Henry Kennedy—chloroform had not been productive of fatal effects. Dr. Stokes, he believed, could mention a case bearing on this point.

Dr. STOKES—The case Dr. Fleming refers to was that of a patient who was subject to the most dreadful fits of cardiac asthma, in many of which death seemed quite imminent, unless he inhaled chloroform. The attacks came on generally six or eight times in the twenty-four hours, and every one of them was met by very copious inhalation of chloroform, which immediately produced great relief, and, in fact, the man went on for four or five weeks, during which he may be said to have lived upon chloroform by day and by night. Upon dissection, I do not think there is any specimen in any of our museums of such extreme fatty degeneration of the heart, and particularly of the right side of the heart.

After a brief discussion Dr. Fleming's suggestion for the appointment of a committee was agreed to. Drs. Morgan, Jacob, McDonnell, and Macnamara, with Mr. Richardson and Mr. Tufnell, were appointed to organise the committee, and it was decided that it should report to the Society next year.

Mr. RICHARDSON said he had for several years used chloroform diluted with an equal quantity of spirits of wine, and he had never seen anything act more satisfactorily. As to the fatality from ether, to which Dr. Macnamara had alluded, these four cases occurred within the space of three months in Boston, and there was also the additional fatal case that occurred in New York, to which Dr. Morgan himself alluded. As regards sickness of stomach he gave ether a short time ago for Mr. Fitzgerald, who was extracting a cataract, and just as the eyeball was opened the woman began to vomit. Mr. Fitzgerald was performing Von Graefe's operation, and owing to the relative smallness of the incision, but little vitreous humour escaped, which probably would not have been the case had the ordinary flap operation been performed, the eyeball being a soft one. He had seen two or three other cases since then of sickness of the stomach caused by ether. He had lately again used the combined chloroform and spirit in four cases, and in none of these was any sickness produced.

Dr. TUFNELL asked Dr. Morgan whether it was safe to use the inhaler in administering ether at night, considering that it was an inflammable fluid?

Mr. MORGAN replied that it was one of the advantages of the inhaler that ether could be used at night with perfect safety, and he had used it at night on several occasions. Mr. Morgan, having expressed his pleasure that a committee had been appointed to consider the subject, proceeded to reply briefly to the objections which had been raised against the employment of ether. Dr. Kidd had mentioned two cases to show that ether caused sickness of stomach. One of these occurred under Dr. Johnstone at the Military Hospital. Dr. Johnstone had written to him asking for the inhaler, because the woman had undergone such sickness for thirty-six hours after chloroform administered during an operation for vesico-vaginal fistula, that he was anxious to try ether on the next occasion. The patient was an hour and twenty minutes under the influence of ether. She vomited twice during the operation, but after it did not vomit at all, and Dr. Johnstone had written a letter thanking him for the use of the inhaler, and expressing his satisfaction with the result. "What I was afraid of (he said) was a repetition of the thirty-six hours of almost incessant vomiting which followed the use of the chloroform four months ago; but I am glad to say that there has not been the very slightest effort at it. She had a most refreshing sleep without any opiate, and presents a very happy contrast to the state she was in the day after the chloroform. There has been neither nausea nor vomiting, no headache, thirst, or fever, and she was quite ready for her breakfast as usual." The other case alluded to by Dr. Kidd was that under Dr. Atthill. The woman did vomit, but she vomited up her breakfast which ought not to have been given her, and the same would have happened with chloroform or any other anæsthetic. He believed the success of ether depended on the non-admixture of atmospheric air, which was effectually provided for by the inhaler. It was this which accounted for the different experiences of Dr. Wilson and Dr. Jacob. The former gave ether on a sponge, which, allowing the admixture of air, caused sickness of the stomach. It was also natural that if a quantity of ether were poured on a sponge and applied suddenly to the patient's face the glottis would resist, and there would be excitement and a struggle. The inhaler obviated all these inconveniences. The vapour was given in the gentlest manner, the patient sank quietly into a state of anæsthesia. There was no excitement, no sickness, and no vomiting. He had used ether in cases in which Dr. Jacob operated, the patients varying in age from a child 8 years old to a man of 76, and nothing could have been more satisfactory. With Dr. Johnstone, in the Military Hospital, he etherised ten patients in an hour for minor operations. Some were etherised sitting in a chair, and in none was there sickness of stomach or any *contretemps* whatever from the beginning to the end. He believed the point referred to by Dr. Kennedy as to the colour of the blood was important. Whether chloroform killed by idiosyncracy or by affecting the heart it was that in amputation of limbs under the influence of chloroform the blood was dark, and under the influence of ether it was a bright red. With regard to the statistics, they had been collected by Dr. Richardson, of London and in America, and according to them the death-rate was 1 in 2,555 in chloroform, and 1 in 23,204 in ether inhalations. A great deal of stress had been laid on the death from ether in New York, but the case when examined was really in favour of ether. The patient was an old man with pneumonia of the lower part of the lung, thickened bronchi, and emphysema. The ether was given to him when he was nearly dying; they restored him and applied it again in ten minutes, and he succumbed. Unquestionably, the statistics were favourable to ether as regarded safety. He had seen 300 cases himself in which ether was employed, and he positively said that sickness was exceedingly rare if proper precautions were taken, and that if given by the inhaler there would be no excitement and no struggle. That day he etherised a patient, æt. 67, for strangulated hernia, and nothing could have acted better; he went off quietly into a sleep, and this man had arcus senilis in both eyes. The day previous he gave ether for the extirpation of the testicle; there was no sickness of the stomach, the gentleman went off quietly to sleep and he said after the operation, "I feel as well as ever I did, and for a bet I would eat a mutton-chop." Another remarkable point about ether was the reaction that occurred directly—there was no depression such as was seen after chloroform, and the pulse, instead of becoming weak and flaccid as in chloroform, became fuller and stronger. After some further observations, Mr. Morgan concluded by expressing his gratification that a committee had been appointed to investigate the question which he had brought before the Society. Meeting adjourned.

STUDENTS' COLUMN.

SYNOPTICAL REVIEW OF THE OFFICINAL PREPARATIONS OF THE BRITISH PHARMACOPŒIA.

By W. HANDSEL GRIFFITHS, PH.D., L.R.C.P., L.R.C.S.Edin.,

Assistant-Librarian Royal College of Surgeons in Ireland.

UNGUENTA (OINTMENTS).

THESE may be generally defined as fatty substances adapted to inunction. In the older Pharmacopœias the so-called "cerates" formed a distinct class; inasmuch as they differ from ointments merely in containing wax (cera), and, consequently, in having a firmer consistence they are now very properly grouped with the latter preparations.

Many ointments become rancid on keeping—an effect at least retarded by the presence of benzoin. Geisler states that the addition of a few drops of nitric ether will remove the disagreeable fatty odour of ointments.

The great majority of the ointments are prepared by simple trituration of the ingredients so as to ensure thorough mixture, but when wax, resins, or concrete oils are to be mixed the aid of gentle heat is necessary. In general terms the following may be said to be the process: The wax or resins and unctious matters are to be melted by a gentle heat, they are then to be removed from the fire, and while cooling to be well and constantly stirred, any dry substances to be added, being meanwhile incorporated in a state of fine powder. Stress must be laid on the direction to employ *gentle heat;* too strong a temperature would cause the formation of acrid acids.

There are thirty-four formulæ for ointments in the present Pharmacopœia. The following classification, based on the nature of unctious ingredient, will be found to simplify the study of them.

CLASS 1.

Ointments—the basis of which is Prepared Lard.

These are tabulated as follows :—

OINTMENT.	STRENGTH.	INGREDIENTS.	BASIS.
U. ACONITIÆ	1 in 60	Aconitiæ, 8 grs, Rectified Spirit, ½ drm.	Prepared Lard, 1 oz.
U. ATROPIÆ	1 in 60	Atropiæ, 8 grs. Rectified Spirit, ½ drm.	
U. IODI	1 in 31	Iodine, 16 grs. Iodide of Potassium, 16 grs. Proof Spirit, ½ drm.	
U. SULPHURIS IODIDI	1 in 17	Iodide of Sulph. 30 grs.	
U. POTASSÆ SULPHURATÆ	1 in 15½	Sulphurated Potash, 30 grs.	
U. POTASSII IODIDI	1 in 8¾ (nearly)	Iodide of Potassium, 64 grs. Carbonate of Potash, 4 grs. Distilled Water, 1 drm.	
U. BELLADONNÆ	1 (of ex.) in 6½	Ext. of Bellad., 80 grs.	
U. HYDRARGYRI SUBCHLORIDI	1 in 6½	Subchloride of Mercury, 80 grs.	

These are prepared by "thorough mixture" by trituration. In the preparation of the first three the solid ingredients, before being incorporated with the lard, are to be well rubbed up with the spirit. In the preparation of *Unguentum Potassii Iodidi* the solid ingredients are to be dissolved in the water before being added to the lard; and in *Unguentum Belladonnæ* also the extract is directed to be first rubbed smooth with a few drops of water.

The use of the iodide of potassium and spirit in making the *Unguentum Iodidi* is merely to aid in the incorporation of the iodine with the basis.

Unguentum Potassii Iodidi would become yellow-coloured on keeping (owing to the liberation of iodine), if free alkali were not present. It is to prevent this that carbonate of potash is employed.

In applying ointments of powerful alkaloids, as of aconitia, the precaution should always be taken of ascertaining that the skin is not abraded.

CLASS 2.

Ointments—the basis of which is Benzoated Lard.

OINTMENT.	STRENGTH.	INGREDIENTS.	BASIS.
U. PLUMBI ACETATIS	1 in 37½	Acetate of Lead, 12 grs.	Benzoated Lard, 1 oz.
U. GALLÆ	1 in 6½	Galls, 80 grs.	
U. GALLÆ CUM OPIO	1 (of galls) in 6½, and 1 of opium in 15	Galls, 80 grs. Opium, 32 grs.	
U. ZINCI	1 in 6½	Oxide of Zinc, 80 grs.	
U. SULPHURIS	1 in 5	Sublimed Sulphur, ½ oz.	

With the single exception of *Unguentum Zinci* the simple direction for the preparation of the foregoing ointments is to "mix thoroughly." In the preparation of *Unguentum Zinci* the lard is to be melted before adding to it the oxide of zinc, and the mixture to be stirred while cooling.

CLASS 3.

Ointment—the basis of which is Prepared Lard, and which also contains Prepared Suet.

OINTMENT.	STRENGTH.	INGREDIENTS.	BASIS, &c.
U. HYDRARGYRI	1 in 2	Mercury, 1 lb.	Prep. Lard, 1 lb. Prep. Suet, 1 oz.

The ointment is prepared by rubbing the ingredients together until metallic globules cease to be visible. The extinction of the mercury is extremely difficult, and is now accomplished by machinery. If a portion of the ointment rubbed on paper shows metallic globules under a magnifier of four powers, it may be concluded that the mercury has not been sufficiently extinguished.

Whether mercury exists in this ointment merely in a state of mechanical division, or in a state of oxidation, is a debated point. The ointment, when first made, is bluish, hence, its common name, "Blue Ointment;" but, on keeping, the colour becomes darker—a change attributable to oxidation; it is very generally believed that the oxide so formed enters into chemical combination with the lard, or one of its fatty acids, indeed, some pharmaceutists contend that the efficacy of the ointment depends upon the formation of this compound.

The use of the suet in *Unguentum Hydrargyri* is to prevent the separation of the metal in warm weather.

CLASS 4.

Ointments—the basis of which is Prepared Lard, and which also contain Olive Oil.

OINTMENT.	STRENGTH.	ACTIVE INGREDIENTS.	BASIS, &c.
U. HYDRARGYRI NITRATIS	1 in 15½	Mercury, 4 oz. Nitric Acid, 12 oz.	Prep. Lard, 15 oz. Olive Oil, 32 oz.
U. VERATRIÆ	1 in 60	Veratria, 8 grs.	Prep. Lard, 1 oz. Olive Oil, 1 drm.

The first of these, commonly known as "Citrine Ointment," is made as follows:—Dissolve the mercury in the nitric acid by a gentle heat; melt the lard in the oil by a water-bath in a large porcelain vessel; mix the two mixtures while hot, and if the mixture does not froth up, heat it until it does; finally stir while cooling.

By the action of the nitric acid on the mercury, pernitrate of mercury is produced, thus,—

$$3\,Hg + 8\,HNO_3 = 3\,(Hg\,2\,NO_3) + 4\,H_2O + 2\,NO$$

When the mercurial solution is mixed with the lard and oil, a reaction also occurs, the nature of which is complicated, and has not been hitherto satisfactorily explained.

Unguentum Veratriæ is made by rubbing the oil and the veratria together, and then mixing with the lard.

.CLASS 5.

Ointments—the basis of which is Prepared Lard, and which also contain Yellow Wax.

OINTMENT.	STRENGTH.	ACTIVE INGREDIENTS.	BASIS, &C.
U. SABINÆ	1 in 3⅜ (nearly)	Fresh Savin Tops, 8 oz.	Prep. Lard, 16 oz. Yellow Wax, 3 oz.
U. TEREBINTHINÆ	1 (oil) in 2⅛	Oil of Turp., 1 oz. Resin, 60 grs.	Prep. Lard, ½ oz. Yellow Wax, ½ oz.

The first is made by melting the lard and wax together by a water-bath, adding the Savin, and digesting for 20 minutes, finally straining through calico.

Unguentum Terebinthinæ is simply made by melting the ingredients by a water-bath, and stirring the mixture while cooling.

CLASS 6.

Ointments—the basis of which is Simple Ointment.

UNGUENTUM SIMPLICIS is made by melting together by a water-bath, and stirring while cooling.—Prepared lard, 3 ozs.; white wax, 2 ozs.; almond oil, 3 ozs.

OINTMENT.	STRENGTH.	ACTIVE INGREDIENTS.	BASIS.
U. HYDRARGYRI IODIDI RUBRI	1 in 28	Red Iod. of Mercury, 16 grs.	Simple Ointment, 1 oz.
U. CREASOTI	1 in 9	Creasote, 1 drm.	
U. CADMII IODIDI	1 in 8	Iod. of Cadmium, 62 grs.	
U. HYDRARGYRI AMMONIATI	1 in 8	Ammoniated Merc., 62 grs.	
U. PLUMBI CARBONATIS	1 in 8	Carb. of Lead, 62 grs.	
U. PLUMBI IODIDI	1 in 8	Iod. of Lead, 62 grs.	
U. ANTIMONI TARTARATII	1 in 5	Tartarated Antimony, ¼ oz.	
ELEMI	1 in 5	Elemi, ¼ oz.	

With the single exception of *Unguentum Elemi* the simple direction for the preparation of the ointments of this class is to mix the ingredients thoroughly.

Unguentum Elemi is directed to be prepared by melting the ingredients, straining through flannel, and stirring constantly while the ointment congeals.

Unguentum Plumbi Carbonatis was the old "Unguentum Cerussæ." *Unguentum Hydrargyri Ammoniati* is commonly known as "White Precipitate Ointment."

CLASS 7.

Ointments—the basis of which is made up of Wax and Oil

OINTMENT.	STRENGTH.	INGREDIENTS.	WAX.	OIL.
U. CANTHARIDIS	1 in 8	Cantharides, 1 oz.	Yellow, 1 oz.	Olive, 6 oz.
U. HYDRARGYRI COMPOSITUM	1 in 4½	Oint. of Merc., 6 oz. Camphor, 1½ oz.	Yellow, 3 oz.	Olive, 3 oz.
U. HYDRARGYRI OXIDI RUBRI	1 in 8	Red Oxide of Merc., 62 grs.	Yellow, ¼ oz.	Almond, ¾ oz.
U. CETACEI	1 in 5	Spermaceti, 5 oz.	White, 2 oz.	Almond, 1 pint.
U. PLUMBI SUBACETATIS COMPOSITUM	1 in 5½	Solution of Subacetate of Lead, 6 ozs. Camphor, 60 grs.	White, 8 oz.	Almond, 1 pint.

Unguentum Cantharidis is made by infusing the cantharides in the oil in a covered vessel for twelve hours, placing the vessel in boiling water for fifteen minutes, straining through muslin with strong pressure, adding the product to the wax previously melted, and stirring constantly while the mixture cools. Olive oil being a good solvent of the active principle of cantharides is now substituted for the boiling water of the older Pharmacopœias.

Unguentum Hydrargyri Compositum and *Unguentum Hydrargyri Oxidi Rubri* are both made by melting the wax with a gentle heat, mixing the oil with it, and when the mixture is nearly cold adding the other ingredients and mixing thoroughly.

Unguentum Cetacei is simply prepared by melting the ingredients by a gentle heat, and stirring while cooling.

The following are the directions for the preparation of *Unguentum Plumbi Subacetatis Compositum*—Melt the wax with 16 ozs. of the oil by heat of water-bath, remove the vessel, and when the mixture begins to thicken add gradually the solution of subacetate of lead, stirring the mixture while it cools, finally add the camphor dissolved in the rest of the oil, and mix thoroughly.

Unguentum Hydrargyri Compositum is a substitute for "Scott's Ointment." *Unguentum Hydrargyri Oxidi Rubri* is commonly known as "Red Precipitate Ointment." This ointment loses its red colour on keeping, owing to the conversion of red to black oxide, or reduction to the metallic state.

Unguentum Plumbi Subacetatis Compositum is a modification of "Goulard's Cerate."

UNCLASSED.

UNGUENTUM PICIS LIQUIDÆ.—Tar, 5 ozs.; yellow wax, 2 ozs. Melt the wax with a gentle heat; add the tar and stir while cooling.

REGISTERED FOR TRANSMISSION ABROAD.

THE
MEDICAL PRESS AND CIRCULAR
is published simultaneously in London, Dublin, and Edinburgh, every Wednesday morning. Price 5d. Post free, 5½d.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6
" IF PAID IN ADVANCE 1 0 0

. Post-office Orders and Cheques to be drawn in favour of—
A. A. TINDALL, 20, King William Street, Strand, London, W.C.
A. H. JACOB, 23 Ely Place, Dublin.
MACLACHLAN and STEWART, South Bridge, Edinburgh.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIERE, Publishers to the Academie de Médicine, Paris—post free in advance, £1 6s. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLMER and ROGERS; Baltimore, by Messrs. KELLY and PIET; Philadelphia, by Messrs. LIPPINCOTT and Co., and DR. BUTLER, post free in advance, £1 6s., about six and a-half dollars; or direct from the Offices in this country for the same amount, by the new Post-office Order system.

WEDNESDAY, JANUARY 8, 1873.

IRISH LUNACY REGULATIONS.

WE devote the utmost space at our disposal in the Supplement of the MEDICAL PRESS AND CIRCULAR of this week, which is occupied by Irish local Medical affairs, to a report of a most important meeting of the Board of Governors of the Limerick Lunatic Asylum. It is hardly necessary to remind our readers that after many weeks of silence succeeding Dr. Nugent's investigation into the management of the Asylum, and without communicating the result of that inquiry to the Board, the authorities decided on prosecuting the warder who was inculpated in the homicide of the lunatic Danford, and gave the Board to understand that they would deal with the subject of the general mismanagement afterwards. The Board, on receiving this intimation, agreed not to press for a further reply to their demands. As, however, Dr. Nugent, the inspector who held the investigation, thought fit to publish in the local papers a letter referring to the Board in terms which they considered disrespectful, and as new horrors in the Asylum had come to light, Mr. De Vere, a most influential governor, submitted to the Board at its last meeting a memorial to the Lord Lieutenant, demanding in the most forcible terms an open, impartial sworn inquiry into the whole matter, and into the conduct of the Inspector not less than any other subject for inquiry.

We regret very much that is impossible for us to lay Mr. De Vere's observations and his memorial before our readers. Every word of them would be instructive to the most uninterested reader, but to those who are acquainted with Irish asylum management—with the progress of the hole-and-corner legislation which has led up to these scandals—and with the magnitude of the interests involved, Mr. De Vere's words are pregnant with force and importance. They are valuable as a loud and influential protest against Dr. Nugent's policy of stripping all extern officers of authority, and investing the resident Medical superintendent and the inspectors with it; and they are doubly important because they were spoken in the presence, and apparently with the approval, of Colonel Monsell, M.P., the Postmaster-General, the Bishop of Limerick, the High Sheriff, the Mayor, and an assembly of the most influential residents in the county.

With the details of Mr. De Vere's speech, and the memorial of the Board we cannot deal here, but we feel bound in duty to ourselves to quote that part of his observations which relates to the existing regulations for the management of asylums, which we have both in years past and recently repeatedly condemned. Mr. De Vere said—

> When these new rules and regulations were introduced, I, and the Board with me, feeling they cast an unworthy slur on the character of this body, and, what was far worse, that they impeded us in our action, and prevented us from exercising our powers of usefulness—that they made us perfect nonentities in the seats we occupied, I had the honour to lay before the Board a series of resolutions on the subject, which were supported by the unanimous voice of this Board. These were laid before her Majesty's Government, but the answer was entirely unsatisfactory. Finding that we were not likely to obtain any redress, I then retired from active participation in the affairs of this Board. I considered the system was so wrong that it was better to let it work out its own condemnation. It has done so, Sir (hear, hear). It has done so fully. It has confirmed the views the Board entertained at that time, and rendered necessary the course we are now about to take. I may have done wrong, I may have done right; but I am merely stating for my own justification, and in explanation to the Board, the reason of my absence from those sittings for a number of years (hear, hear). I was not the only member of the Board who took that course. There were others. There was one especially amongst them—one whose name can never be mentioned within these walls without respect—one whose memory will be always regarded with affection and that reverence which was due to his single-minded honesty, and his singular capacity for business—I allude to the late Mr. Spring Rice (hear, hear). He retired at the same time—I wish to Heaven he was here now to resume that seat, and assist us in our labours (hear, hear). I will not trouble you further. I have said enough.
>
> Mr. De Vere then read the following letter:—
>
> "Mount Trenchard, Foynes,
> "28th February, 1862.
>
> "SIR,—I have to request you to lay before His Excellency, the Lord Lieutenant, the resignation of my seat as a Governor of the Lunatic Asylum.
>
> "Within the last few months an application was made by the Board of Governors requesting to be furnished with a copy of the Rules, then under consideration, which it was proposed to issue for their guidance. With this request the Irish Government did not comply, as a similar refusal to a similar request was, I am told, given to the Board of Governors of the Cork Asylum.
>
> "I have now had an opportunity of examining the new Rules, and the system they establish. They contain matter I strongly disapprove, and omit matter which I think of essential consequence. But if not of more ultimate importance, it is of primary necessity that I should consider the position in which I find myself placed in common with all other Governors of Asylums in Ireland. Our position is, that having been pronounced unfit to be consulted as to the Rules to be imposed, we are, for the administration of these rules, placed practically under the control of the Inspectors. Now, I am of opinion that if the State needs clerks to carry out the instructions of Drs. Nugent and Hatchell, and make reports and returns to

them, the State can afford to pay clerks for the performance of that drudgery; and I consider it simply absurd to expect its execution by Peers, Bishops, Privy Councillors, and principal gentlemen of the district, whose position entails on them many duties, and who in many cases reside at such a distance from the Asylum as makes their attendance at Board Meetings most inconvenient.

"I have the honour to be, Sir,

"Your obedient servant,

"(Signed) STEPHEN SPRING RICE."

Our readers will judge of the force of these communications by the light of the statement, that it is at the present moment under the consideration of the Castle to draw still tighter the narrow limits of authority and interference which are accorded to visiting physicians and Boards of Governors, and hedge in still closer in their irresponsible powers the little family party composed of the inspectors and the resident superintendent, in whom the control of these extensive and valuable institutions, and the discipline and restraint of the lunatic inmates is at present concentrated.

We have every hope that the indescribable *fiasco* at the Limerick Asylum, the partiality of the investigation which followed, and the untimely superciliousness of Dr. Nugent have made such a proceeding impossible.

◆

THE REPRESENTATION OF THE IRISH COLLEGE OF SURGEONS IN THE MEDICAL COUNCIL.

WE learn with much satisfaction that the Council of the College, at its meeting on Thursday last, its attention having been directed to the observations in the MEDICAL PRESS AND CIRCULAR of the 25th ult., on the subject of the illegality of Mr. Hargrave's election, decided to appoint a Committee to confer with the law adviser of the College, with the view of having a case prepared for the opinion of counsel on the subject. The Committee consists of the President, Vice-President, and Mr. Colles. In this action the Council has acquitted itself of a plain duty, and has adopted a proper course in satisfying itself as to the legal authority of Mr. Hargrave's tenure of office. Should it be the opinion of their law advisers that our objection is fatal to the validity of the election, it will be necessary for the Council to proceed at once to the choice of a representative, and Mr. Hargrave will be legally eligible. But if legal opinion should be that Mr. Hargrave was duly elected, the Council cannot forget that its duty to the College will not have been discharged as long as any doubt exists as to their opinion respecting Mr. Hargrave's competency to represent the College, and the Fellows themselves cannot forget that its authority may be required to enunciate their want of confidence (if, as we believe, such exists) in the capability of their representative.

In view of the urgency of the occasion, and the probability of an early session of the General Medical Council, we shall look for prompt attention to the matter by the Committee. The present season is very apt for the obtaining of an immediate consideration of the matter by the law adviser of the College, and the Fellows will be much disappointed if a question of so deep importance to them and their College be relegated to indefinite delay.

THE ROMAN CAMPAGNA.

THE Report of a Royal Commission appointed to inquire into the best means of improving, irrigating, and making salubrious the Campagna, has lately been published by Signor Pareto. From this we glean a few facts which we think may interest our readers. We may set out by stating what many of those who have spent much time in Rome have learned from their pleasure trips, viz.: Instead of being, as too commonly supposed, a flat expanse, unbroken by any elevation, save ruins, or a stray farmhouse, at least two-thirds of the whole, or 335,000 acres consists of hills, and only 14,000 acres can really be called a plain. With respect to the fertility of the soil Signor Pareto concludes that it is on about an average with the rest of Italy, but its products are at present far inferior, owing to the manner in which it is cultivated. Its pastures would not fatten an ox properly. The oxen there can only work seven hours a day, while in other parts of Italy they work ten. The horses are hardy. As to the sheep, Signor Pareto has but little to say in their praise. They are only valuable for their wool; their milk and flesh being alike worthless. From a vivid recollection of the flocks in one of our trips across the Campagna, we should scarcely have thought even the wool worth much. The permanent pastures and meadows are generally found in the low lying lands. Although here and there a meadow is irrigated, in no places is the irrigation perfect, and there are no proper appliances either for distributing the water or for carrying it away. There is no drainage, and in summer all those fields which are not completely flooded in the winter are parched up. The ditches are cleaned by the buffaloes. There is scarcely any native population. The shepherds and labourers are mostly hired from Rome, or the villages around, and stay from October till June. The few who venture to remain are attacked with fever, and if they recover often ruined in health. Signor Pareto is much inclined to believe that the Campagna was always unhealthy.

In support of his views he quotes Horace, Virgil, Livy, Plutarch, and Tacitus, but omits to cite authors telling the other way, viz., Pliny and Stratio. There is no doubt that the climate of the Campagna has been materially altered, since many places which were once renowned for their salubrity are now reckoned among the most pestilential, and *vice versa.* Ostia, Palo, Colonna, are examples of a change for the worse. On the other hand, in ancient times, Virgil, Horace, Livy, Pliny, and others, speak of long snows and the freezing of rivers, and the latter affirms that he could not cultivate the bay without sheltering it in winter. It has often been argued that if the woods which lie along a portion of the littoral parts of the Campagna were no longer allowed to remain swampy jungles, but were reduced to the state of woodlands and plantations; if planting were extensively undertaken along the banks of streams and natural ditches; if drainage were taken in hand, if a greater division of land and a reasonable mode of agriculture were enforced, and labour was made so remunerative that the labourers could live well, eating sustaining food and drinking generous wine; the Campagna would be found not only equal, but superior to many tracts of land in Italy.

It is sad, indeed, that Rome, "the City of the world," now the capital of sunny Italy, should be surrounded by a pestilential desert. In the present state of the country there is no hope of improvement unless the Government take it in hand, and now that the Royal Commission has pointed out the great public works that must be undertaken to make the Campagna inhabitable, we hope they will not be delayed. It would be a better use for Italian money than the large army which costs so much.

REPRESENTATION OF THE UNIVERSITY OF DURHAM IN THE GENERAL MEDICAL COUNCIL.

It is not only in Ireland, we observe, that the choice of a representative in the General Medical Council has produced a storm, for we ascertain from the *Durham Chronicle* that the late election of Dr. Pyle, of Sunderland, in place of Dr. Embleton, has given dire offence. The *Chronicle* says: —

> "How, then, it may be asked, does it come to pass that a gentleman with such negative qualifications should have been preferred to so skilful a man as Dr. Humble? The simple answer is, the genius of jobbery has accomplished it. The professional intellect of Newcastle and the classical intellect of Durham University have been overborne by the stolid qualities of the country parson. Every electioneering device was resorted to in order to secure Dr. Pyle's return; votes were brought from a distance, carriage paid; members of Convocation were created by *ad eundem* degrees, and the payment of fees; and the ordinary members of Convocation were swamped by this sudden irruption of a new force. We do not say these proceedings were illegal; but they were, at any rate, unconstitutional. Lord Brougham once said, when a conflict of opinion arose between the House of Lords and the House of Commons, that it would be perfectly legal to strengthen the House of Lords by the Sovereign marching a battalion of guards into the House and elevating them to the Peerage; but it would be in the highest degree unconstitutional. And so it is that, by a legal, but perfectly unconstitutional, exercise of power, Dr. Pyle has been pitchforked into the General Medical Council, and has thus superseded a very much abler man."

Nor is the *Chronicle* alone in its opinion, for we observe that the *Durham County Advertiser* is equally severe as to the late appointment, and offers as an explanation that a cry was raised to send one of the University's own graduates. For our part we should be glad for the most earnest Medical reformers to be sent to the Council, whether connected with the University or not. It is not alone the corporate interests that ought to be considered. There need be no fear that the Council, as constituted, will lose sight of the claims of any corporation. What we have to fear is that such claims will too long continue to be regarded as of the utmost importance, while the interests of the general practitioners who constitute the bulk of the Profession are simply ignored.

We have nothing to say against the eminent men who now sit in the Council, but great as they are individually as physicians, surgeons, or teachers, they have as a body done very little which calls for admiration or gratitude.

◆

Notes on Current Topics.

The Emperor Napoleon.

On the 2nd inst. Sir H. Thompson performed lithotrity upon the Emperor. Those conversant with the Medical history of the case will not be surprised; for, long before the disastrous war, we had, in conversation with eminent French physicians, expressed the surmise that a calculus was perhaps being formed. Having discussed the matter and other points as to the case with those who knew all its features, we were quite prepared for the news that seems to have taken some by surprise. On the 6th inst. the illustrious patient, under the influence of chloroform, administered by Mr. Clover, was again operated upon by Sir H. Thompson, considerable portions of the calculus coming away. It is highly probable that the patient will yet have to endure another operation before the entire substance is removed. Up to the time of going to press, the case was progressing as well as could be expected, the painful nature of the operations and the age of the patient being considered.

Medical Legislation in Canada.

At the last meeting of the College of Physicians and Surgeons, a committee was appointed to draft amendments to the Ontario Medical Act, to be submitted to the legislature.

One of the clauses of the contemplated amendments proposes an annual assessment on the members of the Profession of two dollars each for the support of the Council. It is also proposed that each member of the College shall receive annually a copy of the *Medical Register* which will contain, besides the names of the registered practitioners, a copy of the Act and other useful information. It is expected that by means of this assessment sufficient funds will be raised annually to meet the working expenses of the Council, without taxing the students so heavily as at present. The Council expects also to be enabled to establish a sinking fund for the purpose of securing a hall in which to hold its annual meetings and examinations.

Signs of Death.

The Academy of Sciences of Paris, in 1870, offered a prize of 20,000 francs for some simple and positive sign of death, which any non-professional person could understand and apply. The most practical and satisfactory one given is mentioned in a late number of Virchow's *Archiv.* It depends upon the fact that no matter how profound the syncope or how death-like the person may appear if the circulation continues, however feebly, the person is not dead. All that is necessary, therefore, is to tie a string firmly around the finger of the supposed corpse; if the blood circulate in the least, the whole finger, from the string to the tip, will swell and generally turn a bluish red. This test is exceedingly simple and conclusive.

Medical Periodicals.

The *Madras Medical Journal* with its November issue utters an expiring groan, heartrending, at least to Editors and Publishers, if not to readers. Our brother of Madras says:—"We cannot go on devoting time and labour—valuable, at least to ourselves—to a task which either the apathy of our Medical brethren or our own incapacity prevents from being so useful as we expected when we began. Our regular contributors may be counted on the fingers; our contributors, regular and casual together, would not need more than the digits of the upper and lower extremities for enumeration. We were careful not to expect pecuniary advantages from our work, by which sage precaution we have evaded disappointment, but we confess we should like to number as subscribers more than 38 per cent. of Local Medical Officers, 17 per cent. of the British Service, 11 per cent. of the Apothecary grade, and 2 per cent. of the Hospital Assistants. Whether our comparative ill-success in meeting with support from our brethren is due to their apathy or our incapacity, we are equally unable to continue our experiment without a larger measure of encouragement than we now receive. If the fault be our own, we have at least done our best—'angels can no more.'"

For comfort to our unhappy contemporary, we can only say that we wish all or any other journal in "the old country" could attain to the percentages which he considers so beggarly. With so good a proportion of patronage we imagine the *Madras Journal* must lay the blame on its financial calculations than on the apathy of its readers or its own incapacity.

Female Medical Students.

THE legal success which the female students at Edinburgh had attained, and which we noticed last week, depended on the failure of the attempt to illegalise the decision of the Managers of the Edinburgh Royal Infirmary, which admitted such students to the practice of the hospital. The resolution adopted by the Board on the motion of Professor Masson, was as follows :—

"That the managers of the Royal Infirmary resolve to admit females already enrolled in the 'Students' Register' for Scotland, to receive clinical instruction at a separate hour from that at which male students are admitted into the hospital, and in a stated number of wards containing not less than eighty beds, to which the female students must confine their visits ; instruct the clerk to issue tickets on these conditions, and remit the following sub-committee to make arrangements, viz. :—Professor Sir Robert Christison, Bart., Dr. Gillespie, Mr. G. Harrison, and Professor Masson, convened."

This resolution only extends to those women "already enrolled," and we may expect that an untiring crusade will yet be fought out by the young "ladies" before they abandon their just claim to participate in the nastiness of the dissecting room. So gross an infringement of the natal privileges of the woman of the period, who is *not* "born to blush," seen or unseen, could not be permitted. Mesdames Woodhull and Claffin, to the rescue ! ! !

Mortality of the City.

FROM the Report of the Medical Officer of Health—Dr. Letheby—just presented, we learn that during the last year the chief causes of death in the City were as follows : —Phthisis 234, tabes and scrofula 88, hydrocephalus 24, pneumonia and bronchitis 326, alvine disorders 51 (39 of which were among children), continued fever 28, scarlet fever 9, small-pox 26, measles 40, whooping-cough, croup, and diphtheria 86, and erysipelas 16—making together 346 deaths from tubercular diseases, 326 from inflammatory affections of the lungs, and 256 from diseases of a zymotic character. In the corresponding period of the last 10 years, the average number of deaths from each of these groups of diseases was 493, 383, and 492 respectively. But, besides these, there were 120 deaths from violence, privation, and poison, against an average of 146, and 97 from convulsions and teething, against an average of 135. To put these results in a simpler form, it may be said that of every 1,000 deaths in the City during the year, 185 were from pneumonia and bronchitis, 133 from phthisis, 50 from tabes and scrofula, 69 from hydrocephalus, convulsions, and teething, 29 from alvine disorders, 16 from continued fever, 5 from scarlet fever, 15 from small-pox, 22 from measles, 49 from whooping-cough, croup, and diphtheria, 9 from erysipelas, 68 from violence, &c., and 350 from diseases of a chronic character. In the case of lung diseases (phthisis, pneumonia, and bronchitis) the proportion has risen from 280, which is the average for the last 10 years, to 318, and in the case of small-pox it has risen from 10 to 15, but all the other maladies are greatly below the average. There has been a falling off in the proportion of deaths from continued fever, scarlet fever, and alvine disorders, thus showing a marked improvement in the public health. This is further exemplified by the returns of sickness among the poor of the City ; for in the year 1872 the number of cases of fever attended by the Union Medical Officers was only 86, against an annual average of 665, and the cases of diarrhœa were only 251, against an average of 927.

Lunacy in Belgium.

AMONG the measures submitted by the Belgian Government to the consideration of the Legislature is one for the more effectual superintendence of lunatic asylums by the State. The law of 1850 did much to improve the condition of the insane, but though the Medical men in charge of an asylum were bound to report any malpractices to the commissioners appointed by Government, they were themselves chosen and paid by the proprietor of the establishment, and were, therefore, his agents rather than those of the public. The new measure gives the government the power of appointing and dismissing the Medical staff.

The "American Journal of Obstetrics."

THE last quarterly number of the *American Journal of Obstetrics* contains a number of articles of very unequal merit, and we must say that, although that journal professes to be the "only one of its kind in the English language," the Transactions of the Obstetrical Societies of Dublin, London, and Edinburgh furnish materials, which for professional interest, philosophical treatment, and scientific value, will fairly compare with the contents of "the only journal of its kind." But a familiar song teaches us, that every one who seeks improvement should "step across to Yankee land." The journal before us certainly contains many *words* not familiar to us, and which we think unnecessary, *e.g.*, Phrenopathics, phreniatrics, putrilage, electro-atrics, electro-pædiatrics, and many others which have useful and familiar synonsms. We read of a "ligatura caudens" (sic), and as the monstrosity recurs on the same page, as "caudela caudens" (sic), we presume it is considered deserving of attention. The report of Dr. Ullersberger, on the use of electro-therapeutics in the diseases of children, is certainly not calculated to inspire much confidence in his knowledge or judgment. Dr. Munde, contributes an article on the employment of the curette in the treatment of uterine cancer, as invented by Recamier, and specially employed for this object by Prof. Simon, of Heidelberg. "The object is," says the author, "to scoop the morbid product out of the normal tissue."

Happy the man who could effect this? Still Dr. Munde believes that "unfortunately a cure of the carcinoma" is impossible. The advantages of the method are stated to be, that caustics produce evanescent effects, and inconvenience and danger. Strange to say, however, Dr. Munde recommends, after the use of the curette, "a fluid caustic of greater or less strength to be applied, such as chromic, carbolic, or proligneaus acid." After several days, we will find "a smooth soft surface, covered with healthy granulations, or already in process of cicatrization." We need quote no further. An important discussion at the Philadelphia Obstetrical Society, on the use of obstetric forceps, elicited a strong feeling in favour of their early and general use. Dr. Robertson contributes an article on the obstetric forceps, descriptive of a modification introduced by him in their construction.

Angina Pectoris.

Angina pectoris, when not resulting from organic disease of the heart or great vessels, but as a simple neurosis, may be successfully treated by the induced current, as recommended by Duchenne, Trousseau, Ullersberger, and others. L'Ippocratico mentions a case of a man, æt. 48, cured rapidly this way, the positive pole being applied to the left nipple.

Floating Hospitals.

Paris is the centre of revolutions. Dr. Rochard has suggested the establishment of a floating hospital in that city, for lying-in women. We fear many years must elapse before such a project can be entertained in this country. Such is the state of pollution of our rivers, that we scarcely have one that would float a tub, near a large town, on which a sojourn of many days would be agreeable. Even the sea is poisoned with sewage near most of our great watering places.

Inunction of Mercury.

Dr. J. Neumann states his belief (in the *Oesterr Zeitschr f. prakt. Heilk*), that mercury employed by inunction, as grey ointment, traverses the uninjured skin. His reason is that, a few weeks after the inunction, the mercurial globules are no longer to be found in the follicles. He adopts Voit's assumption, that it is in the form of sublimate that the resorption takes place.

The Amount of Caffeine Contained in Coffee, and on its Physiological Action.

Although the quantity of caffeine contained in raw coffee is known, no attempt has ever been made, says Mr. Hermann Aubert, in the *Journ. Chem. Society*, quoted by the *Pharmaceutical Journal*, to ascertain how much of the alkaloid is contained in a cup of coffee, and it is also uncertain whether the beans should be slightly or strongly roasted, and whether the ground coffee must be boiled to extract its active principles or simple infusion is sufficient. By extracting the coffee with water, either by percolation or decoction, and evaporating to a syrup, which is then treated from five to eight times with chloroform at nearly 60° till all the caffeine has been dissolved out, he obtains a larger quantity than previous experimenters. Raw beans of the yellow Java kind yielded 0·709-0·849 per cent. by this method, while they gave only 0·474 by Garot's method of precipitation with basic lead acetate. When much roasted, coffee loses a certain quantity of caffeine, which sublimes, whereas it loses none by slight roasting. Notwithstanding this, the coffee made in the usual way by percolation from strongly roasted coffee contains rather more caffeine than that made from an equal weight of slightly roasted coffee, as the roasting renders it more easy to extract.

When coffee is prepared in the usual domestic fashion by pouring six to ten times its weight of boiling water three or four times over ground coffee, nearly the whole of the caffeine is extracted, hardly one-fifth of it remaining in the grounds. The quantity of caffeine in a cup of coffee prepared from 16⅔ grams of coffee is about 0·1 to 0·12 gram. A cup of tea prepared in the ordinary way from 5-6 grams of Pekoe tea contains also about 0·1 to 0·12 grams of caffeine. Caffeine acts upon the spinal cord and causes tetanus in doses of 0·005 gram for a frog, injected subcutaneously; for a rabbit, 0·120 gram (injected into the jugular vein); for cats, 0·200, injected in the same way; and the same quantity for dogs. It has a peculiar action on the muscles of frogs, especially when directly applied to them, causing them to become rigid and white, apparently from coagulation of the myosin. It does not exert this action on the muscles of mammalia. The tetanus is removed by artificial respiration, and if this process is kept up for about a quarter of an hour, no recurrence of the tetanus takes place, even though the respiration is then discontinued, showing that the caffeine is quickly eliminated or destroyed in the organism. Occasionally it produces a paralysis of the hind legs in rabbits, but the author is uncertain to what cause this is to be attributed. It quickens the heart and at the same time reduces the blood pressure. This effect he believes to be due to stimulation of the cardiac ganglia, combined with diminution of what he regards as cardiac *tone*, due to paralysis of the nerves passing from these ganglia to the muscular substance.

The action of caffeine, says Mr. Aubert, does not explain the stimulating and reviving action of coffee. We may therefore, presume that there is, in his opinion, still much to learn respecting the effects of this substance on the body.

Medical Periodical Literature.

We had imagined that this market was pretty well stocked already, with four old-established weekly journals, three or four good monthlies, besides the quarterlies, half-yearly abstracts, and the innumerable volumes of hospital reports, society proceedings, &c. Yet still they come, and the mushroom existence of a dozen previous attempts seems not to deter others from "seeking glory at the cannon's mouth." Last week two fortnightlies made their *début*, one in London, the other in Dublin, headed respectively *The Student's Journal and Hospital Gazette* and *The Irish Hospital Gazette*. There is nothing striking in the appearance or features of either journal to lead one to suppose they are intended to run a lengthy existence, but we wish them success. They are evidently amateur speculations, and the title of each fairly bespeaks its contents. Yet still another! *The Medical Record* is to see the light to-day, and to be continued weekly until further notice. Of this, therefore, it will be premature to pass an opinion until we see it.

This much we can say, that its programme is almost a copy of the monthly periodical, *The Doctor;* that it is to be under the distinguished guidance of the present editor of the *British Medical Association Journal,* who will therefore have two irons in the fire. We understand it to be the intention of the promoters that our contemporaries and ourselves be quietly "snuffed out and decently buried," "but the end is not yet." *Pabulum Acherontis!*

Royal College of Surgeons in Ireland.

At a meeting of the Council held January 2nd, it was unanimously agreed to that the emolument of Dr. W. Handsel Griffiths, assistant-librarian, should be increased from £100 to £150 per annum. We understand that Dr. Griffiths is at present actively engaged in compiling for publication, an index to the catalogues of the library. This index is to be in two parts, an index to authors, and an index to subjects; it will prove a great boon to the numerous fellows, licentiates, and students by whom the libraries of the College are frequented.

The Meeting of the Medical Council.

It is announced that the Executive Committee of the Medical Council will hold its meeting on Tuesday next. The date of the assembly of the entire Council will be then decided, and it will depend in great measure on the completion of the Irish Conjoint Examination Scheme. We have reason to believe, that since an understanding was arrived at between the University of Dublin and the two Colleges, the College of Physicians has made a communication to the other parties to the compact suspending, in some respect, its judgment in the matter. We believe this step is not to be considered as a check in the perfecting of the arrangement for a conjoint examination, but only as a measure of diplomatic precaution, pending an official notification of its intentions by the University.

Very Early Intelligence.

Our contemporary, *The Medical Record,* has distinguished its *début* by a piece of clairvoyance which will probably surprise no one more than the eminent physician who is the subject of it. Our contemporary is published on Wednesday; on Tuesday morning the London daily papers announced on the before-mentioned authority, that "Sir William Jenner was *last night* elected President of the Pathological Society of London." Now as this Society did not meet until Tuesday night, our juvenile contemporary, in its anxiety to get noticed in the newspapers, took the election into its own hands and relieved the Fellows of all right of selection or trouble in the matter. Comment is superfluous.

The Lectureship on Practice of Medicine in the Ledwich School, Dublin.

We learn that the Joint Lectureship in the Ledwich School, vacated by the election of Dr. Little to the Professorship of Practice of Medicine in the School of the Royal College of Surgeons, will not be filled up. Dr. Henry Eames will henceforth be sole lecturer on the subject in the Ledwich School.

We are glad to hear that Dr. Brewer, M.P., is expected to be able to return to England shortly.

Relapsing fever is again in London, more cases having been reported.

Mr. Henry Hancock will deliver the Hunterian Oration at the Royal College of Surgeons on the 14th February next, the day being the anniversary of the birth of John Hunter.

Dr. Adolpho E. Peralta, Professor of Materia Medica, Therapeutics, and Hygiene in the University of Buenos Ayres, died on the 20th of October.

The U.S. Pharmacopœia is now in the hands of the binders, it is confidently expected to be ready for delivery within a couple of weeks. The nomenclature adopted is that of Attfield.

The Medical commission sent by the Transcaucasian Government to investigate the origin of the plague in Persian Koordistan, reports that it followed the opening of two old plague pits, in which the victims of the plague which devastated Koordistan in 1829-32 were interred.

The Medical Society of the College of Physicians, Ireland, will hold its third meeting this evening (Wednesday) at eight, the chair to be taken at half-past eight, p.m., when the following communications will be read:—

Dr. James Little, "On the Use of Digitalis in the Failing Heart and Delirium of Acute Diseases."

Dr. Grimshaw, "On a Case of Aneurism of the Basilar Artery."

The next meeting of the Dublin Obstetrical Society will be held in the Royal College of Physicians on Saturday, Jan. 11th, when papers will be read by—

Dr. Hemphill, "Abstract of Midwifery Cases."

Dr. Johnston, "Clinical Report of the Rotunda Lying-in Hospital for the Year ending November, 1872."

Dr. Morgan, "On Specific Inflammation (dactylites) of the Hands and Feet in Children."

Dr. J. More Madden, "On Certain Improvements in the Long and Short Forceps, and on their Use in Midwifery Practice."

An inquest was held on Monday, in the Limerick Workhouse, upon the body of a man named Flanagan, whose death was caused by a fall from a car, resulting in an extensive depressed fracture of the skull. It appears that the deceased was picked up by the police, and was conveyed to Barrington's Hospital, where he was seen by the resident physician; but that gentleman, finding the man extremely violent, decided on sending him back with the police, intimating at the same time that his condition was not without danger. The unfortunate man, suffering, as the event proved, from an immense depressed fracture of the skull, was then "walked" back to the police-station in Coloony Street, a distance of nearly a mile, at one o'clock in the morning, and was confined in a cell until the opening of the police-court, where he was charged with having been "drunk and disorderly." The presiding magistrate happened to be Dr. O'Shaughnessy, who at once perceived that the prisoner was suffering from some cerebral injury, and had him conveyed to the workhouse hospital.

Correspondence.

THE MEDICAL COUNCIL AND THE DUBLIN COLLEGE OF SURGEONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read with anxiety rather than curiosity your frequent observations on the present representation of my college on the Board of the Medical Council. I am little conversant with Medical politics, but entertain an old regard for the college, and not a little pride in the degree which I hold from it, and I am made aware by the London journals that sooner or later, but within a few months, its interests will be at stake in the Medical Council or in Parliament. Under such circumstances I should desire the college to be spoken for by a delegate who combines experience and tact with energy; and I don't understand a servant of the college clinging to an office to which he is no longer able to do justice. As I am not a young man myself, I should desire to respect the feelings of a Nestor like Mr. Hargrave, who, at least, has been always "true blue." But I think that gentleman's loyalty would be somewhat tarnished if he allowed his love of office and its emoluments to overcome his regard for the college. If, however, it should appear that Mr. Hargrave does so, I shall not flinch from publicly accepting my share in the responsibility which your correspondent, "A Fellow of Fourteen Years' Standing," has asked the college to undertake.

If you, sir, and your correspondent of last week consider an assembly of the college necessary, I shall be prepared to attach my name to a requisition for that purpose.

Yours, &c.,

A FELLOW OF 1844.

MEDICAL ETHICS AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I see it announced that at the last meeting of the Council of the College of Surgeons of England Mr. Charles Hawkins carried a resolution, which is intended to be condemnatory of the practice of advertising Medical works in the *non-Medical press.* One might fairly start by asking, which is the Medical and which the *non*-Medical press? seeing that in the columns of the daily press even the heads of the Profession do not hesitate to discuss almost any matter relating to medicine and disease, and that the editors of the daily journals also write upon questions which affect our body, as well as the public health, quite as freely, and with as much ability as their brethren of the so-called Medical press. If it is an offence against good morals to advertise a book in the public papers, surely it is not less so to have the names of eminent physicians and surgeons paraded day after day at the tail of a bulletin of health of my Lord Duke. Again, who is to draw the line between a book on sanitary matters, written with the ostensible purpose of advertising the author, although professedly in the public interest, and another on diseases of the lungs, or auscultation and percussion, on diseases of the eye, the ear, the heart, &c.? Surely, one has as much to do with the public health as the other? Who are the greatest offenders in this particular matter? For an answer to this query look down that list of Messrs. Churchill, which so often occu-[illegible] a prominent column in the *Times*, and you will see the [illegible] of the Profession figure there quite as frequently as [illegible] it is intended to put down or stigmatise in this [illegible]-worded resolution. Why, let me ask, is there more [illegible] from whatever point of view looked at, in an adver-[illegible] of a book in the columns of the *Times*, or other [illegible], than in that *placard* which stares one in the [illegible] down the Strand, professing to announce the [illegible] of the last number of a certain journal which [illegible], but which it is well known is in great [illegible] artfully-contrived puffs of the little clique called [illegible]," and the few friends admitted to the charmed [illegible].

It is all very well for such men as Mr. Hawkins, who have been fortunately born with a *silver spoon* in their mouths, and never having perpetrated the enormity of writing a book to advertise, to endeavour to impose their code of ethics on less fortunate members, doomed to earn their bread by the sweat of the brow. If Mr. Hawkins will put the young and struggling members of our Profession in a fair way of earning a livelihood, and providing bread for themselves and families, by means which he considers perfectly legitimate, and more certain of attaining this object, I daresay they will only be too glad to adopt his method, whatever it may happen to be. Perhaps the College will not object to found a fund to help young men up the hill, or assist those when going down. At all events, they will not, I daresay, object to pass a rule which shall compel members of Council to retire from so lucrative a position at a sufficiently early age to make room for their younger brethren. If sixty is thought to be the right age for a man to retire from hospital work, surely the same rule holds good for the Council of the College and its Examining Body.

One word more—if not at all derogatory on the part of members of the clerical and legal professions to advertise their works in the columns of the daily newspapers, why is it so for the Medical? Is it fair or reasonable to impose moral and ethical restraints upon us, which are considered quite uncalled for by the sister professions? These have their special organs; nevertheless, the works of the archbishops and the Lord Chancellor more frequently appear in the list of advertisements in the daily newspapers than those of the Medical Profession. Then why seek to impose restraints which are in no way required or thought of by professional bodies standing quite as high, if not higher, in public estimation? The fact is, our colleges are growing more nice than wise, and wasting valuable time over trifles, while they habitually neglect or postpone the consideration of the true interest of the Profession.

I remain, Sir,

Your most obedient servant,

A HARD-WORKING PRACTITIONER.

Medico-Legal Intelligence.

CREDULITY INCREDIBLE.

A CORRESPONDENT has sent us the Hull local papers, which contain one of the most barefaced cases of extortion we have ever met with in the annals of quackery. It appears that, for a long time a person named Jackson, who had dubbed himself with the usual "Doctor," was in the habit of obtaining large sums of money from persons who had, or fancied they had, an ailment of one kind or another, for his "Indian Medicines," &c. Last week this said individual was brought to a sudden stop in his career of rapid fortune-making; and although we condemn the scoundrel as one of the worst of his class, we have, nevertheless, no sympathy with the fool who allowed himself to be the victim of so palpable a piece of fraud. The evidence is of such an extraordinary character that we are sure our readers will freely give the space it occupies.

The prosecutor, John Richardson, farmer, Easington, deposed that in the early part of last year he saw in the shop of the defendant a bill about Professor Jackson and his Indian remedy. He went into the shop and asked for a bottle of the Indian remedy, but was told that may be it would not suit him, as he was in a bad way. He was given a glass tube, and told to blow through it into water. When he blew, the water turned immediately like milk. The prisoner then told him he was in a very bad state, it was time to say his prayers, as he should not live over two or three months. It alarmed him very much. He then told witness he had just strength in him to master the disease. Witness was given another tubular glass with a red fluid in. He had to hold one end in his hand. He was told that the fluid did not boil, and that he had no circulation of his blood, which was then dying for want of circulation. He was given a third tubular glass with a bulb at each end. He held one end in his hand, and was told his heart had no regular stroke, and went 120 a minute. Witness was told all these glasses were specially sent to the prisoner from India, and were invented specially for the Prince of Wales when he was ill of a fever. At the first interview he agreed to supply medicines and attendance at £2 2s. a month, extras to be paid for at cost price. Witness was to have the balsam as it came from the merchants — unadulterated. Remembered purchasing of the prisoner a box, on the inside of the lid of which were the words "The Great Indian Remedy." He paid £25 for it, and £2 carriage from India. He was shown the invoice for the goods, and would not have purchased if he had not believed it came from India, and was worth the sum stated. On another occasion he purchased "The Indian Medicine Chest." The lid was covered with tinfoil, but on a portion of the covering being removed a picture became visible, and the words "improved Swiss bricks" were to be seen, showing it had been a toy box. There were also marked on the lid £20 16s. 6d., the cipher being marked in lead pencil. He paid that amount for the box, and £1 3s. 6d. for carriage from India. A smaller box was in the larger box, and had a coat of arms on the lid to show it came from India. The coat of arms had been rubbed off and the word "glove" was now visible. Inside the smaller box was an inscription, "the great Indian remedy, the blood, the wonder of wonders." There were also two trees, which represented trees of life. He took the contents of the twenty-four bottles which were in the box, and took the empty bottle back to prisoner to be refilled. He paid £3 10s. for the refilling. He was told this manna or the bread of life was what the Israelites used in the wilderness, and a very small quantity of it would keep a person alive for days if they had no other food. Was told the head man amongst the balsam merchants of India had taken it and lived to the advanced age of 170 years. He believed this, and was shown a letter from a man to Jackson stating that his father had lived to the advanced age of 170, and that he (Jackson) was to be the only agent in England. Understood the man was an Egyptian, named Smith.

The Recorder—The name of Smith is very like Egyptian.

Mr. Seymour, to Prosecutor—Did you believe that the portion of manna which you got was a portion of that which the children of Israel had eaten, or rather left?

Witness—Yes. Prosecutor told him that the manna he sold was rained from heaven, and was gathered regularly from the trees.

Mr. Seymour—How could the children of Israel pass through British India?

Witness—Oh! the trees were propagated. In re-examination, last witness identified the cheques he had drawn upon his bankers, and that the only medicines which he took were "the bread of life" and sarsaparilla.

The evidence of two members of the Profession was here put in, which proved that the so-called medicines were utterly valueless, the most celebrated of all being spring water coloured with cochineal.

The Prisoner was sentenced to twelve months' hard labour.

◆

Medical News.

Royal College of Surgeons of England.—At a special meeting of the Council last week, the 2nd inst., Mr. Luther Holden, F.R.C.S., Senior surgeon to St. Bartholomew's Hospital, was elected a member of the Court of Examiners, to fill the vacancy occasioned by the resignation of Mr. John Adams, consulting surgeon to the London Hospital. A letter was received from a member of the College, expressing regret for his unprofessional advertisements, and it was resolved in consequence to stay further proceedings. The following motion by Mr. Charles Hawkins was carried:—"That the practice of frequently advertising Medical works in the 'non-medical Press' is, in the opinion of the Council of the Royal College of Surgeons of England, not conducive to the honour or dignity of the Medical Profession."

The Royal Humane Society will shortly establish a receiving house near Waterloo Bridge.

Small-pox still rages at Whitehaven. 451 cases have occurred in connection with the Infirmary and Brausty Hospital alone, and probably as many more in the town at large.

General Medical Council.—The Executive Committee of the Council will meet on the 14th inst., when the date of the assembly of the Medical Council will probably be fixed.

Publicans and Drunkards.—The number of persons licensed to sell intoxicating liquors, who were convicted in England and Wales from 1st July, 1870, to 1st July, 1871, for permitting drunkenness on their premises, appears, from a Parliamentary return, to have been 301.

At the annual meeting of the Surrey magistrates held last week, it was recommended that an analyst be appointed for the country, with the following scale of fees:—For the first 100 cases in any one year, £1 for each case; for the second 100, 10s. each; and if the number should exceed 200 in the year, then 5s. each for cases above 200; and further, that the inspectors of weights and measures be appointed to procure samples of food, &c., and be allowed £1 in each case of conviction. The fee for any private person who wished to have any analysis made was fixed at 10s.

Royal Infirmary, Edinburgh.—It has been intimated to the managers of the Royal Infirmary of Edinburgh, that the residue of the estate of the late Mr. Buchanan, of Dura, which has been left to the Infirmary, amounts to fully £18,000, and that the money will shortly be paid. The legacies paid to the Infirmary during the three months beginning October 1st, last, when the accounts for the past financial year were closed, together with those intimated, but still outstanding, amount to £26,397.

Medical Wills.—Last week, the wills of two members of the Profession lately deceased, were proved in London. That of Dr. C. Lister Wall, late of Kensington, under £35,000, and Mr. Partridge, F.R.S., late Consulting-surgeon and Professor at King's College Hospital, and resident in Brook Street, Grosvenor Square, under £20,000.

◆

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a relpy in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this request.

All communications intended for insertion must bear the name and address of the writer; not necessarily for publication, but as a voucher of good faith.

Subscriptions in the United States.—A correspondent has drawn our attention to the fact, that some of the houses in the United States are charging the enormous figure of 15 dollars per annum (more than £3) for supplying this Journal to different parts of the States. We beg, therefore, to state that we shall be happy to supply the same regularly, post free, per annum, if paid in advance, for considerably less than half this amount, viz., six and-a-half dollars (about £1 6s. 0d.), either direct from our offices in this country, or through our recognised agents in the United States.

Lectures on Diseases of Women.—A course of lectures will be commenced at the Royal Hospital for Women to-morrow (Thursday) week, by Dr. Alfred Meadows, to which members of the Profession are admitted on presentation of their card. The subject of the first two lectures is "Fibroid Tumours of the Uterus."

Guy's Student.—Mr. Bellamy's Text-book of Anatomy, referred to in our issue of the 18th ult., is published by Messrs. Baillière, Tindall, and Cox. The other work you mention was published years ago, and is of little use now.

Querist (Birmingham).—Like you, we are curious to know the result. Time only can answer your question definitely.

Dr. Waring Curran.—Many thanks.

Dr. T. H. Marshall.—We shall be happy to send to your address in Germany.

Dr. P.—Your indignation is very just, but so long as there are persons so utterly devoid of common sense, so long will there be plenty of knaves to take them in. You will find the case in another column; but we are absolutely sick of protesting while the law remains in its present unsatisfactory state.

Enquirer.—Ulceration of the cartilages of the knee-joint may undoubtedly be present in a strumous patient suffering from phlegmasia dolens, but as a coincidence only. But we cannot think our correspondent's patient suffered from such lesion, as he states she is "getting better quickly." Phlegmasia dolens may occur at any period of pregnancy, in the unimpregnated state; or even in the male. Therefore, as our correspondent's conclusions may be erroneous, we advise him to let his patient have time and rest.

The "British Medical Journal" and Trade Dodges.—Our contemporary is loud in vituperation against the *Lancet* for giving [illegible] reviews for the sake of advertisements. It is the old tale of the pot calling the kettle black; in fact, we should be sorry to think the *Lancet* could be guilty of such flagrant venality as its accuser has lately exhibited—as an instance of which, a facetious correspondent sends us the following clipping from the first number of *The Students' Journal*, which he characterises as *un bon mot*:—

> "D. D. D.—Your whiskey is evidently a 'New Invention.' Write to the *British Medical Journal* and send a sample. We don't know their terms for advertising."

QUACK PROSECUTION FUND.—The honorary secretary to this fund writes:—

> "As you were good enough to notice the successful efforts (conducted by the solicitors to the Society for the Suppression of Vice) to suppress a villanous form of quackery, in your issue of December 18, I take the liberty of bringing the claims of the *Quack Prosecution Fund* before you. I regret to say that the response made to the private application by circular has not been so generous as one could wish, indeed, it barely amounts to £100. Up to the present time we have proceeded with three cases only, though we have the evidence prepared for several others, and only wait for funds."

The promoters of this fund have our entire sympathy, and we trust that our readers who have the interests of the Profession at heart, will liberally support them in their endeavours to remove so great a scandal from our midst. To this end we shall be happy to receive and acknowledge contributions, however small, which may be sent to either of our offices.

VACANCIES.

St. Thomas's Hospital, S.E. Botanical Lectureship at the College (See advt.)

Cheltenham Hospital. Resident House-Surgeon to the Branch Dispensary. Salary £120 per annum. Application to the Secretary.

Royal Infirmary for Women, Waterloo Road, London. A Physician and a Surgeon.

Nottingham. Medical Officer of Health for the Borough. Applications for particulars to be addressed to Mr. S. G. Johnson, Town Clerk.

Meriden Union, Fillongley district, Coventry. Medical Officer. Salary £30, exclusive of fees.

St. George's Dispensary, Regent Street, W. Physician-Accoucheur.

St. George's Dispensary, Hanover Square. W. Dispenser.

Coleraine Union, Portrush Dispensary district. Medical Officer. Salary £70 per annum, exclusive of fees. (See Advt.).

Manchester Royal Infirmary Dispensary and Lunatic Asylum. Two Assistant-Physicians; two Assistant-Surgeons; one Obstetric Surgeon; Ophthalmic Surgeon, and Dental Surgeon. These appointments are all honorary. Applications must be sent in before the 18th inst.

Nottingham General Hospital. Resident Surgeon Apothecary. Salary £150, with board and washing. Applications to be made to the Secretary at the Hospital.

District Lunatic Asylum, Ireland, Londonderry district. Resident Medical Superintendent. Applicants must be qualified in Medicine and Surgery. Applications to Dublin Castle. (See advt).

Sligo Union. Sligo Dispensary District. Qualified Apothecary. Salary £80 per annum. (See advt.)

Inishowen Union, Clonmany district. Medical Officer. Salary £90.

Mullingar Union, Tyrrell's Pass District. Medical Officer. Salary £110.

Rathdown Union, Powerscourt district. Medical Officer. Salary £110.

APPOINTMENTS.

BANKS, W. M., M.D., F.R.C.S E., L.R.C.S.Ed., Surgeon to the County Prison at Kirkdale, Lancashire.

BLACK, M., M D., C.M., L.M., Medical Officer, &c., for the Strangford Dispensary District of the Downpatrick Union, co. Down.

CALLENDER, G. W., F.R.S., F.R.C.S., Surgeon to St. Bartholomew's Hospital, Consulting Surgeon to the Charterhouse.

CREIGHTON, Dr., Surgical Registrar to St. Thomas's Hospital.

EDDINGTON, Mr. J. E., House-Surgeon to Addenbrooke's Hospital, Cambridge.

FARREN, N., L.R.C.P.Ed., L.F.P. & S. Glas., Medical Officer, &c., for the Buncrana Dispensary District of the Inishowen Union, co. Donegal.

GORDON, J. H., M.D., Medical Officer for District No. 6 of the Alderbury Union, and a Medical Officer to the Wiltshire Friendly Society.

HOLLINSHEAD, F., M.R.C.S.E., Medical Officer of Health for the King's Norton Rural Sanitary District.

HUGHES, H., M.R.C.S., Medical Officer of Health for Bethesda, Bangor.

KENNEDY, T. A., L.K.Q.C.P.I., L.R.C.S.I., L.M., House-Surgeon to the Western General Dispensary, Marylebone Road.

MAGEE, R. J., L.R.C.S., Medical Officer to the Fever Hospital, Gowran

RIORDAN, T. T., M.D., L.F.P. & S. Glas., Medical Officer for the Marksbury District of the Keynsham Union.

SARVIS, T., M.D., Public Analyst for Bethnal Green.

THORPE, Prof., Analyst for the City of Glasgow.

TYRRELL, Dr. T. P., Medical Attendant to the Convict Prison, Spike Island, Queenstown.

MEETINGS OF THE LONDON SOCIETIES.

WEDNESDAY, January 8.

EPIDEMIOLOGICAL, 8 P.M.—Dr. Buchanan "On the Concurrence of Epidemics."—Dr. Squire "On the Periods of Infection in Epidemic Disease."

THURSDAY, January 9.

ROYAL INSTITUTION, 3 P.M.—Professor Odling "On Air and Gas."

FRIDAY, January 10.

CLINICAL SOCIETY, 8½ P.M.—Annual Meeting for the Election of Officers and Council.—Mr. Callender, "On a Mode of Dressing Wounds."—Dr. Lockhart Clarke, "On a Case of Cysts in the Cerebellum."—Dr. Edis, "On a Case of Right Hemiplegia occurring during Pregnancy, with rapid Recovery after Parturition."

MONDAY, January 13.

MEDICAL SOCIETY, 8 P.M.—Ordinary Meeting.

TUESDAY, January 14.

ROYAL MEDICO-CHIRURGICAL, 8 30 P.M.

Marriages.

BETHELL—WOOD.—On January 1st, at Langley Burrell, Wilts, Alfred Bethell, M.R.C.S., of Bridgnorth, to Kerew, eldest daughter of W. B. Wood, Esq., of Langley.

MORISON—DEANS.—On January 2nd, at St. Thomas's, Southwark, J. W. Morison, M.R.C.S., to Mary, daughter of the late Thos. Deans, Esq., of Westminster.

JOHNSTONE—BOND.—On December 28th, at St. George's, Hanover Square, London, Dr. H. J. Johnstone, of Dublin, to Gertrude, eldest daughter of L. M. Bond, Esq., Philadelphia.

RENTZSCH—RUMSEY.—On December 28th, at St. Mary's, Boltons, G. H. Rentzsch, M.R.C.S., of Chelsea, to Fanny, daughter of the late A. Rumsey, Esq., of Fulham.

Deaths.

GURNER.—On the 29th December, at the Royal College of Physicians. Pall Mall East, Florence, the tenderly-beloved and only daughter of William and Mary Gurner, aged 16.

LEECH.—On the 19th December, at Abbeyleix, Jonathan Leech. M.D., F.R.C.S.I., Surgeon to the Queen's Own Royal Dublin Militia.

MILLER.—On the 29th November, at Baroda, A. H. Miller, L.R.C.P.Ed., Residency Surgeon, aged 30.

HANDYSIDE.—On 23rd December, very suddenly, at St. Petersburg, James Ronaldson Handyside, M.D.

SEPPINGS.—On the 19th December, E. Seppings, M.R.C.S.E., of Swaffham.

SHAW.—On the 18th November, at Port Stanley, Ontario, C.W., C. Shaw, M.D., L.R.C.S.Ed.

WESTMACOTT.—On the 29th December, J. V. L. Westmacott, M.R.C.S.E., of Ardwicke, Manchester, aged 26.

Advertisements.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.
The next PROFESSIONAL EXAMINATION for the MEMBERSHIP will commence on THURSDAY, Jan. 23.
Candidates are required to give fourteen days' notice in writing to the Registrar of the College, with whom all certificates and testimonials required by the by-laws are to be left at the same time.
Pall Mall East, 1873. HENRY A. PITMAN, M.D., Registrar.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.
FIRST or PRIMARY PROFESSIONAL EXAMINATION for the LICENCE.—The next Examination will commence on Monday, Feb. 3rd. Students are admitted to this Examination after the termination of the Second Winter Session of Professional Study at a recognised Medical School.
SECOND or PASS EXAMINATION for the LICENCE.—The next Examination will commence on Monday, Feb. 10th. Gentlemen who have completed four years of Professional Study according to the College regulations are eligible for admission to this Examination.
Registered Medical Practitioners, qualified before January, 1861, are admitted to examination under special by-law.
Candidates are required to give fourteen days' notice in writing to the Registrar of the College, with whom all Certificates and Testimonials required by the by-laws are to be left at the same time.
Pall Mall East, 1873. H. A. PITMAN, M.D., Registrar.

APOTHECARIES' HALL, BLACKFRIARS.—The next Examination in Arts will be held at the Hall on Friday and Saturday, 24th and 25th JANUARY, 1873. A Syllabus of the Subjects for Examination may be had on application.

An Examination in Arts will again be held on the 25th and 26th of April, 1873.

R. H. ROBERTSON, Secretary to the Board.

ST. THOMAS'S HOSPITAL MEDICAL AND SURGICAL COLLEGE. The BOTANICAL LECTURESHIP in the College is VACANT. Gentlemen anxious for the appointment, are requested to forward their applications to R. G. Whitfield, Medical Secretary, on or before Friday, the 10th January, 1873.

THE HOSPITAL FOR WOMEN, SOHO SQUARE.

A Course of LECTURES will be delivered at the Hospital during the months of January, February, and March, 1873.

Dr. ALFRED MEADOWS will lecture on "Fibroid Tumours of the Uterus," on Thursdays, January 16th and 23rd.

Dr. HEYWOOD SMITH, on "Cancer Uteri" on Thursdays, January 30th and February 6th.

Mr. CHRISTOPHER HEATH, on "Diseases of the Female Urinary Organs" on Thursdays, February 13th and 20th.

Dr. ARTHUR W. EDIS, on "Miscarriages" on Thursdays, February 27th and March 6th.

Dr. SQUAREY, on "Ovaritis and Ovarian Dysmenorrhœa" on Thursdays, March 13th and 28th.

Each Lecture will commence at 8.30 P.M. Gentlemen proposing to attend can obtain Cards of Admission on application to HENRY B. INGRAM, Secretary.

DISTRICT LUNATIC ASYLUMS, IRELAND.

THE OFFICE OF RESIDENT MEDICAL SUPERINTENDENT of the DISTRICT LUNATIC ASYLUM, LONDONDERRY, being now vacant, Candidates for that office are requested to forward their testimonials, with a statement of their peculiar qualifications for the appointment, to the Under Secretary, Dublin Castle, on or before the 15th day of JANUARY next, in order that the same may be submitted to His Excellency the Lord Lieutenant.

Applicants must be duly qualified to practice both in Medicine and Surgery, and registered as such under the Medical Act of 1858.

Candidates are requested to specify their age.

The Candidate who may be selected for the office in question, will have to enter upon his duties forthwith.

Dublin Castle, 28th December, 1872.

CONWAY GRAMMAR SCHOOL.—During the last two years, Boys from this School have passed the *Preliminary Examinations* of "*Physicians and Surgeons*," *Glasgow*; "*Apothecaries' Hall*," *London*; and the "*Incorporated Law Society of Great Britain.*" Inclusive terms for boarders £8 per quarter. (*Classics, Mathematics, Modern Languages, Music, and Drawing*). Sea and mountain air.

Address, Mr. Fawcett, Conway, North Wales.

SLIGO UNION—SLIGO DISPENSARY.

THE SLIGO DISPENSARY COMMITTEE will proceed to elect a qualified APOTHECARY, on the 17th instant, at 12 o'clock, at a salary of £80 per annum. Candidates are requested to lodge their Testimonials with the Honorary Secretary, on or before the 16th instant. Personal attendance required on the day of election, and age not to exceed 40 years.

DANIEL MACGILL, Hon. Sec.

Sligo Dispensary.
2nd January, 1873.

WANTED, by a Married Gentleman, aged 38, of active habits, accustomed to good society, and of ability and experience in his profession, an ASSISTANTSHIP in a good Practice preparatory to Partnership (or ultimate succession) if mutually desirable. Address by Letter (Principals only) to "S. A. S.," 4 Albert Place, Rothesay, Bute Island.

THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.

Patron:—H.R.H THE PRINCE OF WALES.

This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develope the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £35 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote.

Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c., can be had at the office,

40 MOLESWORTH STREET, DUBLIN,

W. O'NEILL, Secretary.

THE Friends of a YOUNG GENTLEMAN, who labours under occasional MENTAL HALLUCINATIONS, are anxious to place him in the family of a Medical Gentleman, who will undertake the treatment of his case.

For particulars, apply to Dr. Hadden, of Skibbereen.

TO PHYSICIANS.—The friends of a Lady whose mind is occasionally affected, desire to place her in a PHYSICIAN'S FAMILY, where she would be treated with care and kindness, and have a happy home. Please state Terms in reply. References given and required.—C. E., Donoughmore, Co. Tyrone.

JOSEPH GILLOTT'S
STEEL PENS.
Sold by all Dealers throughout the World.

THE EARL STREET MEDICAL AND DRUG HALL.

J. LEONARD and CO. beg to inform the Medical Profession and Public in general that they have become Proprietors of the above old established Concern, recently in the possession of the late Mr. J. King.

In addition to the usual supply of Drugs and Family Requisites for which this Establishment has been long celebrated, J. L. and Co. have the pleasure to announce that, being Licentiate Apothecaries, they have opened a Compounding Department for the dispensing of Prescriptions under their own immediate supervision, with Medicines of the purest quality, and they trust that this arrangement will be found a great convenience not only to the numerous customers of the Establishment, but also to the inhabitants of the north side of the City.

May 8, 1872. 19 NORTH EARL STREET, DUBLIN

ASTHMA—SLADE'S ANTI-ASTHMATIC CIGARETTES after having been submitted to many careful trials, are found to be safe, efficient, and agreeable, are now daily prescribed by the most eminent Physicians treatment (specially) ASTHMA, and other Bronchial and Pulmonary Affections. In Bottles, at 2s. 9d., 4s. 6d., and 11s.

Prepared by THOMAS SLADE, Pharmacian,

118 LONG ACRE, LONDON.

A liberal discount allowed to the Wholesale Houses, the Profession, Hospitals, Infirmaries, &c. Wholesale Provincial Agents:—Bewley & Draper, Dublin; Raimes & Co., Edinburgh, Liverpool, and York, Jewsbury & Brown, Manchester: Charles Britten, and Banks & Richards; Birmingham.

MEDICAL DEBT RECOVERY OFFICES,

13A Great George Street, Westminster, S.W.

MR. W. T. PEACOCK, AGENT, COLLECTOR, AND ACCOUNTANT, begs to intimate that he continues to devote his personal and careful attention to the Recovery of Debts.

MEDICAL PRACTITIONERS, in TOWN or COUNTRY, who are unable to obtain a settlement of their claims within a reasonable period, will find, by availing themselves of Mr. Peacock's services, they will ensure an economical, prompt, and efficient mode of recovering their outstanding accounts.

Terms and references on application, or sent post free.

The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements, from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

☞ Advertisements for Insertion in this Journal must be at the Office, on Saturday, by Two o'Clock.

INJURIES OF THE SPINE, THE RESULT OF RAILWAY CONCUSSIONS.

BY J. MORGAN, M.D., F.R.C.S.I.,

Surgeon to Mercer's Hospital, and Lecturer on Surgical and Descriptive Anatomy R.C.S.I., &c.

"Mental sufferings, bodily pain and disability, and complete annihilation of the prospects of a life, weigh lightly in the scales of Justice, which are only made to kick the beam by the burden of the actual money loss entailed by the accident." So writes Mr. Erichsen in his remarks on railway injuries, when referring to the unfortunate and too frequent results of shock received in collisions, or of accidents which jar the spine and lay the foundation of the gradually culminating train of miseries which by degrees overwhelm the sufferer. Railway accidents have been a fertile source of litigation; no doubt in some instances the injuries received have seemed trivial, and the damages awarded excessive, yet in others, the compensation given has appeared totally inadequate to the sufferings which were necessarily entailed. This irregularity of justice seems chiefly due to the want of due appreciation of the nature of the injury inflicted, and of the progressive course which the deterioration of the bodily health and physical condition may pursue; much more will probably depend on the representation to the jury by an earnest and astute advocate, of the hardship done to a commercial interest, such as a railway company, than of consideration for the sufferings and disability which have been caused to a fellow-creature. It is natural that jurors should but little appreciate the nature of the injury done, or understand the delicacy of the parts concerned, and the difficulty of treatment which such a complex and highly sensitive structure as the spinal cord would present; and where they hold the balance of award it is still more difficult for them to understand that an injury caused at a certain epoch may pass apparently harmlessly by, and yet, after a shorter or longer time, it may be assigned as the absolute cause of a long enduring and gradually aggressive course of symptoms, which undermine the health, and either have left at the time of the inquiry unquestionable evidences, or, according to the experience of Medical men, will gradually and more remotely develope themselves with a sure but more stealthy tread. The difference of opinion which Medical evidence presents on some of these inquiries is widened by the method of cross-examination by the contending advocates, who can cull Medico-legal extracts suited to their purpose, and can propose *ex parte* suppositions in support of or against the plaintiff as the case may be, while the actual condition of the patient, *in esse* or *in posse*, is too often lost sight of during the heat of debate and of the consideration of suppositions and often inapplicable cases.

The remarkable and now well established fact that a considerable time may elapse between the receipt of an apparently harmless injury and the development of symptoms which are in all probability essentially fatal, helps in no small degree the difficulty of forming a judgment, while, on the other hand, the cupidity of litigants doubtless may magnify an otherwise trivial injury, and they may succeed in mulcting the company assailed. It seems to me that public companies would fare much better by leaving, when it is possible, the question to the arbitration of properly selected Medical men on both sides, who would candidly and impartially examine the condition of the patient, and forecast the probabilities as to ultimate injury to the health. On the one hand the company should fairly compensate a *bonâ fide* injury, and should even allow extra compensation in consideration for the uncertain ultimate results of such injuries; on the other hand they would escape the excessive awards given in cases where no permanent injury has been done, yet where the injured person would gladly have compounded. I have no doubt myself that if such a course were adopted a considerable saving to the company and the subscribers would accrue.

The well-known aphorism, that "no injury of the head is too slight to be despised," applies equally, if not more forcibly, to the spine; the effect of concussion, whether received by railway or other injuries, is ever a cause of concern, as not only may the symptoms come on at the time of the receipt, but they may be postponed considerably.

A remarkable example is given by Mr. Erichsen, which will exemplify the immediate results and the remote effects of such an accident:—

"A gentleman in felling a tree was struck in the back part of the head and between the shoulders by a large bough; complete paralysis of sensation and motion of all below this was the immediate result. Respiration, circulation, digestion, secretion, and assimilation, were all normal, even his weight increased. He was possessed of unusual mental vigour though in this deplorable condition, and was in the habit of travelling, lying on his back in his carriage. In 1851, six years afterwards, as his lower limbs remained in the same condition, he applied to several sources to have them both amputated. The surgeons hesitated at such a procedure; at length he succeeded in having the desired amputations performed, and both his limbs were removed near the hip-joints without the slightest pain or even tremor of a muscle. The stumps healed well; he resumed his wandering life and died in 1852 of disease of the liver, brought on by excesses in drink. No *post-mortem* was made."

This case exemplifies the undoubted receipt of an injury, its immediate and remote results, and yet that it did not of itself prove fatal.

The following, however, illustrates the uncertainty of the effect of such spine concussions, and is perhaps the more important in a Medico-legal point of view:—

A wine merchant, æt. 43, healthy and active, was in a railway collision; he was dashed forwards and then rebounded; he extricated himself, and found himself, he thought, unhurt, and he was engaged a couple of hours in assisting his fellow-travellers. It was not till his return home that evening that he felt uncomfortable. Grave symptoms gradually developed themselves indicative of spinal injury, and in one year and nine months after this he is reported as an invalid, shattered in health, and quite unequal to attend to business of any kind. His case was the subject of trial, and he was awarded £6,000 damages (a), which might at first sight appear unusual in amount, but when the nature of the accident and its probabilities are considered, it cannot be considered so, for one in his position and dependent on his own exertions.

The following very interesting case came under my own observation, and represents an intermediate condition, the effects of the injury were both immediate and remote. The symptoms became grave and augured badly, and yet the patient has gradually improved:—

It was tried at the Wicklow Assizes in June, 1868. The plaintiff succeeded in his case, and recovered from the company the sum of £400, instead of £50 lodged in court by the defendants. He was a tall, powerfully-built man, unmarried, 50 years of age, and managed a coal store of his own. It was proved in evidence that he was in perfect health at the time of the accident, and that three weeks previous to it he had walked seven miles in one hour and forty-five minutes, and up to the time of the accident could lift sacks of coal or assist in the coal store. On the day of the accident he had left town well, and proceeded till a shunting took place. There was a delay, as some carriages had to be removed; the train had just started and the plaintiff was sitting with his back to the engine, with his right arm and shoulder over the back rail, looking at people in the seat behind him. Immediately after the starting a severe shock was felt, his back and side were driven against an opposite fellow-traveller, he received slight injuries on the face; at the moment, he stated, he was affected with extreme difficulty of breathing and gasping for breath, just as if struck suddenly over the pit of the stomach. The officials wanted him to leave the carriage and come into the station-house (which the train had hardly passed when the shock by running into some empty carriages occurred), but he felt so ill he could not stir, and he preferred going to his home about seven miles further on. He felt much prostrated; his stomach was sick; he felt pain chiefly in his back, and was much agitated and depressed. He went on to his station, and to his home, about half-a-mile further on, by car, into which he had to be helped. On arrival there he was helped and almost lifted from the car to a sofa, where he lay much depressed. A doctor was sent for, who shortly arrived, and gave wine, &c.; the patient was not able to leave his bed for twelve days, requiring to be almost lifted to the sofa; he was confined to the house eight weeks. He then was able to go out for very short periods, chiefly sitting in the open air, or resting with one knee on the ground, or lying on the ground. He gradually improved till he could go a little about the farm, lying down frequently whenever the pain was too severe, but not able to do any kind of work. At the time of his examination by me, five months after the accident, he presented the following evidences:—He still suffered from pain down the back and thighs, and was particularly annoyed by a pain shooting from his back to his breast-bone; he was troubled with shortness of breathing ever since the accident, his legs were weak, and he had constant pain in the back; he could not stand upright, and in order to obtain ease when standing he was obliged to assume a peculiar position. He would grasp the right thigh firmly with the right hand, and place the left arm horizontally across his back; by this means he relieved the spine from much direct weight. Unless in this posture, he could not stand up even for a very few moments; he preferred to walk rather than drive in a car, but he could only walk a very short distance, till he was obliged to rest. The breathing was short and difficult; there was a tightened band sensation round the waist. He sweated profusely both night and day, and he had become emaciated, having lost one and a-half stone weight during the few weeks he was confined to the house; he had lately also darts of pain from the spine up to the head.

The conclusion I arrived at, and in which I was supported by two co-professionals of experience, was that the man had received a concussion of the spine, modified probably by his peculiar position at the time of the accident, and by the slow rate at which the train was moving, as it was but emerging from the station; that he had undergone, no doubt, much physical suffering; that the continuance of the symptoms in so marked a degree and so long a time after the accident, rendered it very difficult to say what the result of his case would eventually be; but that complete recovery (which could by no means be promised with certainty), could not be hoped for under the most favourable circumstances, until a considerable time had elapsed; that freedom from any exertions or possible strains, and abstention from the active pursuits of his former life would form a considerable item in his ultimate recovery.

I have this month inquired into the patient's condition since the accident; he has gradually recovered, but still complains of the dorsal weakness and pain.

Some of his symptoms were remarkable; the profuse diaphoresis was particularly so, it seemed to be constant, and even in the open air and when at rest, he was bathed in perspiration; the darting post-sternal pain towards the spine was also most marked and distressing, pressure about the middle dorsal vertebræ aggravated the sensation. Although this patient has so far recovered, it will hardly be questioned that his case was one of gravity, and that the sum awarded but poorly compounded for the sufferings and risk to which he was exposed. It is worthy of note that the position he was in at the time of the accident was peculiar, and in itself may have contributed to his being so injured from apparently not a severe concussion.

(To be continued.)

(a) Erichsen.

CLINICAL REMARKS ON THE VALUE OF STRYCHNIA IN WHITE-ATROPHY OF THE OPTIC NERVE.

By Jabez Hogg,

Surgeon to the Royal Westminster Ophthalmic Hospital, &c.

The atrophic changes seen in the internal eye are among the most palpable, and at the same time the most important, which the ophthalmoscope has revealed to the ophthalmic surgeon. Atrophy of the optic nerve arises from a variety of causes, some of which, when seen and recognised in an early stage, are amenable to Medical treatment, whilst in by far the larger number of cases, and especially those which have failed to receive early and due recognition of the gravity of the disease, it is almost hopeless to look for any efficient aid from therapeutics. Of late, however, an attempt has been made to vaunt the efficacy of strychnia, as a remedy in every form of atrophy of the optic nerve.

Professor Nagel, of Tubingen, published in the *Centralblatt* marvellous results obtained by the use of strychnia in cases of "functional and organic diseases of the optic nerve and retina," in which relief appeared to follow the first hypodermic injection of a fraction of a grain of the drug. Dr. Chisolm, of Baltimore, America, also, in *The American Journal of the Medical Sciences*, records several cases of cures effected by its administration, either by the mouth or by injection; and he says "he was prepared for the striking results which followed its use in Nagel's hands from having previously obtained speedy relief in functional disturbances of the nerve, amblyopia, &c." On a review of these cases it does appear that he has forgotten that amblyopia, amaurosis, anæmia, &c., must rather be regarded as symptomatic of a diseased condition—functional derangement—than as a disease, *sui generis*, and, therefore, I cannot avoid the conclusion that some error has occurred in describing or classifying such cases among "organic degeneration of the optic nerve, known as white-atrophy." I am, in a measure, strengthened in this view, for Dr. Chisolm in his papers appears to have first made trial of strychnine in cases of night-blindness. He has put on record three cases of this disease, "of varied duration, but which obtained speedy and permanent relief by the hypodermic use of strychnia." Hemeralopia, or night-blindness, is almost always a functional derangement of vision, and is invariably improved or cured by the exhibition of tonics, change of food, and rest. I have never seen in any single case that I can call to memory this eye-affection end in white atrophy. Another case related by him was one, he says, of "choroido-iritis of two years' standing," and the patient had "floating muscæ, with extensive patches of atrophy scattered about the fundus," &c. This patient was evidently labouring under a form of disease which, although it leads slowly to changes in the retina and choroid coats, never terminates in what is recognised as white atrophy. I am, therefore, strongly of opinion that the cases in which the administration of strychnia has been found useful are those for which tonics, nervine tonics as they are called, of any kind will do a great deal of good.

The cases which in my experience more frequently end in white atrophy are those having a cerebral origin; but then these have never been benefited in any way by such a drug as strychnia, indeed, they are more likely to be aggravated if its use be persisted in. Neither is it useful in the atrophy which is seen to follow in the train of glaucoma. The atrophy of which, by the way, differs from the former in as much as the optic disc is more irregular as the vessels of the choroid become more involved. Nor is it useful in choroio-retinitis, the atrophic mischief in which involves the retinal vessels; these are much diminished in calibre, although not wholly lost, even when considerable maceration has taken place. Neither is it serviceable in the atrophy which sometimes follows syphilitic retinitis, myopia with posterior staphyloma, and albuminuric degeneration. The atrophy in the latter disease presents well-marked retinal and peri-papillary degeneration, with the remains of fatty and hæmorrhagic patches distributed over the fundus. In none of these diseases have I found strychnia, whether administered by the mouth or hypodermically, of any service. I propose to give a few brief particulars of cases in which I have tried the administration of the drug both internally and hypodermically, and you will then be enabled to form some opinion of its value as a remedial agent.

Case I.—*Unrecognised Meningitis ending in White-Atrophy of the Optic Nerves.*

Raphael J., æt. 26. Ten years ago was sent by his father to a merchant's office at Liverpool. He was then a strong lad, and in tolerably good health, but, as was supposed, from the close confinement to office work, he soon suffered from severe headache, throbbing of the temples, and occasional sickness. He became very drowsy, and was often found asleep at his desk. He would fall asleep while writing a letter, with the pen firmly fixed between the fingers, as in the act of writing. He was then obliged to go to bed, and frequently slept for seventeen hours. and when awoke he had an inordinate appetite. He applied to a Medical man in Liverpool, and under his treatment obtained temporary relief. At Christmas time he came up to London, and, while seated at his father's dinner table, was seized with sickness and vertigo, and was obliged to be led from the room. This attack passed off. The next day it was noticed that he squinted, and he complained of seeing double. Leeches, blisters, and other remedies afforded partial relief, but at the end of a week he again had a violent vomiting fit, and a sudden darting pain appeared to pass through his head and eyes, entirely depriving him of sight. Several eminent physicians were consulted, and after some weeks of treatment his sight was partially restored; he could distinguish the articles of furniture about the room, and even the face of his watch. A slight relapse brought on a fainting fit, and this ended in almost total blindness. He was seen by several ophthalmic surgeons, but does not remember whether they pronounced his case to be one of "optic neuritis." A Medical galvanist subsequently tried the current for a week or two, but as no benefit was derived from it the hypodermic injection of strychnia was proposed. I was consulted about this time, and, finding almost every remedy had failed and that he was now suffering from white-atrophy, I said it might be as well to try this drug, and it was accordingly employed for more than two months. Minute doses were injected about the temporal region, near the entrance of the frontal nerve, and in the arms alternately, until unpleasant twitchings and other symptoms arose, and the use of the drug was obliged to be discontinued. Not the smallest benefit was obtained.

He has since suffered from attacks of sick headache, which are always associated with a perverted sense of smell. His intellect is, however, perfectly clear and good, and, since he became blind, he has acquired considerable skill as a musician, but he remains in a hopeless state of blindness, and the optic discs are pearly white, the vessels of the retina coursing over them unchanged.

Case II.—*Unrecognised Meningitis ending in White-Atrophy.*

Emma W., a domestic servant, was sent up to the hospital from the country, having only a faint perception of large objects. She had suffered from headaches and sickness, but the symptoms failed to attract attention, until one day she complained of being unable to see her way about the house. The discs presented the appearance of consecutive atrophy; their peripheries were blurred and irregular. She was otherwise, at the time, plump and in good health, a slight headache only continued to trouble her. Various remedies were tried, but without benefit, and, as the discs were becoming paler, I thought some good might be obtained by the injection of strychnia, and 1-40th of a grain was injected night and morning into the temples. This was gradually increased until 1-5th of a grain was reached, but not the slightest change or improvement followed, although it was continuously used for upwards of two months. The local irritation produced by the salt at times gave trouble and pain to the patient, but only once or twice did twitchings and jumpings of the limbs annoy her. The galvanic current was then tried with and without full doses of quinine and other tonics, and the external application of veratria for about another two months; the atrophy, nevertheless, became more palpable, and she was discharged hopelessly blind.

CASE III.—*Atrophy of the Nerve supervening on an attack of Paralysis. Paraplegia of the Lower Extremities, with Optic Neuriits.*

R. G., æt. 54, July 1863; had been under Dr. Brown-Séquard for some months, by whom he was sent to me. The history of the case was, that he had some three years before suffered great prostration from repeated hæmorrhoidal losses of blood. On one occasion a "slight fainting fit" supervened, and from that moment he gradually lost power over his lower extremities. About the same time the sight of the right eye became so weak that he could scarcely see tolerably sized print, and the left eyes as gradually began to decline while he was under treatment. Dr. Brown-Séquard sent the patient to me; the right eye had already passed into a state of atrophy, while the left remained at the earlier stage—that of optic neuritis. The disc was much choked, and he could only distinguish the outline of large objects and nothing more. His general health had much improved, his appetite was good, he slept well, &c. This had been brought about by iron, strychnia, and various tonics prescribed by Dr. Séquard, but as the sight had rather declined than improved, it was agreed to try the iodides in various forms and the galvanic current. No good was done, and at the end of a month's treatment the left eye had become quite dark; the ophthalmoscope showed that atrophy was only somewhat less advanced than in the right. It was, therefore, decided to return to strychnia and iron internally, and to combine with these the hypodermic injection of minute doses of strychnia beneath the skin of the extremities. This was continued for some weeks, but not the slightest improvement took place, and towards the end of the year a severe hæmorrhage from the lower bowelj occurred, was followed by a paralytic seizure, and death supervened in a few days. In this case strychnia was employed in the first instance with all the subtlety and skill possessed by that eminent physician, Dr. Brown-Séquard, but without the slightest benefit to the patient's sight.

◆

CASES IN PRACTICE.

Reported by JOHN W. MARTIN, M.D., M.Ch. Q.U.I.,
Assistant Medical Officer to the Mayfield Factory Dispensary, Portlaw, late Assistant Surgeon to the North Tipperary Light Infantry Militia.

CASE IV.—*Pericarditis, Pneumonia, and Albuminuria.*—Bridget Kirby, æt. 40, wife of a carpenter. (Notes taken November 11th, 1872, on the eighth day of illness.)

Heart and Circulatory System.—Heart's action very rapid; its impulse scarcely perceptible at the apex; fremissment over the area of the impulse; the sounds of the heart altered; the second sound is not heard in the usual position, opposite the second intercostal spaces, over the base of the heart; it is heard very faintly at the articulation of the fourth rib, on the left side with the sternum; the first sound is shortened, distant, and very indistinct; the area of precordial dulness is enlarged to a diameter of four inches by four; it extends upwards as far as the upper border of the fourth rib, and towards the right, to the right margin of the sternum; the slightest attempt at movement induces violent fits of palpitation; she is obliged to sit up constantly in the bed, supported by pillows; pulse 108 small, regular, and very compressible.

Respiratory System.—Respirations twenty-eight per minute, laboured and sighing; she is troubled with a short, hard, hacking cough, unattended by any expectoration; there is slight dulness over the interscapular region, especially upon the right side, and over the inferior angle of the right scapula, with tubular respiration, and well marked bronchophony; resonance over the anterior surface of the chest unaltered; respiration puerile; no crepitant, sibilant or sonorous râles.

Digestive System.—The tongue clean and moist at the edges, furred in the centre, firm and well protruded; anorexia; no thirst; bowels have been confined for four days.

Genito-Urinary System.—Passed about eight ounces of urine in the twenty-four hours; the specimen examined was heavily laden with urates, and albuminous.

The Nervous and Integumentary Systems normal.

History.—A broken down, unhealthy-looking women, addicted to "stimulants," and of improvident habits; living in a state of great wretchedness. Present attack commenced upon Monday, November 4th, with swelling in the left side of the face, and in the arm and leg on the same side. On Friday, November 8th, the œdema subsided; about four o'clock in the afternoon she felt a severe pain in the head, which lasted until eleven p.m., when she was suddenly seized with a violent pain in the right side, in the axillary region; the subcutaneous injection of a quarter of a grain of morphine in solution, gave immediate relief from this pain; she passed a quiet night, free from pain or distress.

Saturday morning, Nov. 9th.—The pain returned in her side; she vomited frequently; felt great pain in the epigastrium and cardiac region, accompanied by tenderness to pressure over the ensiform cartilage, and at the point of impulse; respiration became difficult, with a slight hacking cough, unaccompanied by any expectoration. She was treated for the pulmonary symptoms, with hot turpentine stupes, linseed meal poultices, and a mixture containing, ant. tart., vin. ipecach., and tr. aconiti, until Monday, Nov. 11th, when a closer examination revealed the state of the heart.

Treatment.—A blister 4 by 3 inches, applied to the precordial region; the hot poultices to the side, to be continued, and the following mixture and pills to be taken:—

℞ Potassii iodidü, ʒj., tr.;
Tr. Aconiti, ʒj.;
Syrupi, ℥ss.;
Aquæ, ad. ℥viij.

M. Two tablespoonfuls to be taken three times a day.

℞. Pil. scilla et digitalis, āā gr. j. One to be taken three times a day.

Nov. 12th.—Passed a bad night; was unable to lie down; the recumbent position inducing severe dyspnœa; the blister acted well, but was applied below the left mamma, not, as directed, over the lower portion of sternum; the cardiac sounds are improved in character; there is great difficulty in feeling the heart's impulse; complains of a sense of weight in the epigastrium and region of the heart, but is free from all pain; the slightest exertion induces violent fits of palpitations; tongue clean; the bowels acted freely once in the twenty-four hours; passed only about five ounces of urine, heavily laden with lithates, and albuminous; treatment continued.

Nov. 14th.—Feels much relieved; able to lie down; slept fairly during the night; passed about sixteen ounces of urine; respiration easier; sense of oppression in the epigastrium diminished; palpitations less frequent; capable of making some exertion; treatment continued.

Nov. 15th.—Slept well; feels much better; lies easily in the recumbent position; the heart's sounds stronger and clearer; pulse 120, improved in volume and tone; area of cardiac dulness diminishing; tongue clean; bowels acting; treatment continued.

Nov. 16th.—Lies comfortably upon the right side; the tongue clean and firm; no longer suffers from the cardiac distress; she is conscious of a tendency to rave, especially when inclined to sleep; bowels acting regularly; dulness over the cardiac region diminished, reaching only as far as the middle of the fourth intercostal space, and towards the right side as far as the median line of the sternum; heart sounds improved, clear, distinct, and stronger; urine no longer albuminous.

Nov. 18th.—Out of bed and dressed; expresses herself as feeling much better; cough less troublesome; has no headache; bowels acting regularly; passed about a pint of urine; treatment continued.

Nov. 19th.—Improvement steady; is up and about every day for a little; area of cardiac dulness greatly diminished; the percussion strokes are followed by greater resonance, even over the parts where it still continues; both sounds of the heart distinct, rhythm normal, their tones improved; heart's impulse felt against the walls of thorax; pulse 84, increased in volume and tone; passing urine freely; it continues free from albumen; continue treatment.

Nov. 27th.—Area of cardiac dulness reduced to its normal extent; first and second sounds of the heart have become quite clear and natural in rhythm and tone; pulse full and regular, 68 per minute; has been able to resume her ordinary household duties; feels her strength returning; continue treatment.

The subsequent history of this case was one of steady convalescence; its chief interest lies in the well-marked character of its symptoms, and its favourable progress under treatment. Had the woman's constitution been stronger, and the inflammatory symptoms more urgent, I might have adopted the mercurial treatment so strongly recommended by Graves; but, taking all the circumstances of the case into consideration, I decided upon the milder course, which, in this instance, answered most admirably.

(*To be continued.*)

LECTURES ON HUMAN ANATOMY (*a*).

By Walter Rivington, M.S., Lond., F.R.C.S., Eng.

Surgeon to the London Hospital and Lecturer on Anatomy at the London Hospital Medical College.

Lecture I.

Man's place in Nature—The Human Skeleton—The Vertebral Column—General Characters of a Vertebra—Transcendental Anatomy—Theory of Archetypes.

Gentlemen,—Natural objects are arranged in three great groups—Animal, Vegetable, and Mineral—and these groups are dignified by the name of Kingdoms. The Animal Kingdom was divided by Lamarck into two Sub-kingdoms; the first comprising all those animals who possess what is popularly known as a backbone or vertebral column, and who by right of that possession are called Vertebrates, and the second comprising all those animals who are destitute of this column, and hence called Invertebrates. But the employment of a mere negative distinction such as the absence of a backbone to bind together the heterogeneous groups included under the term Invertebrate was felt to be a lazy, unsatisfactory, unphilosophical method. Moreover, Cuvier pointed out the marked anatomical distinctions between large groups of the Invertebrates and broke them up into the Mollusks or animals with soft bodies like the snail, the Articulates or animals with segmented and jointed bodies like the lobster, and the Radiates, animals presenting a rayed or radiated appearance, like the star fish. Since Cuvier's time other classifications have been proposed, and his "radiate mob," as Professor Huxley terms it, has been effectually destroyed. The classification which finds most favour now is that of Huxley, to whose work on "The Elements of Comparative Anatomy, 1864," or the later "Introduction to the Classification of Animals" I must refer you for details which would here be out of place.

The Vertebrate Sub-kingdom is divided into five *Classes*—Mammals, Birds, Reptiles, Amphibia, and Fishes. The Class of Mammals to which man belongs, is distinguished by the possession of organs called mammary glands, which, in the female, secrete milk for the nourishment of the young. The term mammalia is derived from the Latin word *mamma*, signifying a pap or teat.

Mammals, again, comprise several groups called *Orders*, the highest of which is named Primates, and includes all the Monkeys, the Apes, and Man (*a*). From their resemblance to man the highest Apes are called anthropoid Apes, and of these there are four distinct kinds, the Gibbons and Orangs inhabiting Eastern Asia, and the Chimpanzees and the Gorilla inhabiting Western Africa. Whether there are any anatomical characters sufficient to justify the separation of Man from the man-like Apes is a question which has given rise in our day to a warm—nay, a bitter controversy. Those interested in the discussion may consult on the one hand Professor Owen's work on "The Comparative Anatomy and Physiology of the Vertebrates," and on the other, Professor Huxley's book on "Man's Place in Nature." *We* must be content to take man as we find him and study him apart from his congeners. To study him most conveniently will be to examine first that part of his organisation by virtue of which he has a right to be placed in the Vertebrate Sub-kingdom. The fabric of all vertebrate animals is built upon a hard internal structure formed of bone and called the skeleton (from the Greek *σκελετος*, which means dried up, dry, or parched, and in the neuter was applied to a dried body, a mummy, but never to the bony framework which we term skeleton) (*a*). This skeleton is composed of a number of separate pieces or bones united together either by flexible tissues called ligaments (from the Latin verb *ligo, ligare*, to bind), or by a mechanical interlocking of their edges called sutures (*sutura* from *suo* to sew). The mode of union varies much and produces the different kinds of joints or articulations which are designed to permit movements between the parts of the skeleton. These movements are effected by means of organs called muscles (from *musculus* a little mouse, a muscle, &c., &c.), red fibrous structures attached to the bones at each end, free to move in the middle, and possessing the vital property of being able to contract or shorten under a stimulus such as is usually conveyed to them by nerves distributed from the great nervous mass called the central nervous system, but better known as the Brain and Spinal Marrow. To protect the brain and spinal cord or marrow is one great office of the central and main part of the skeleton of all vertebrates. The Vertebral Column is this main part—a central axis made up of separate bones called Vertebræ consisting of two symmetrical halves and supporting three bony cavities or capsules, the Skull above, the Thorax in the centre, and the Pelvis below. Looking at the skeleton you cannot fail to observe what we term its bilateral symmetry, the repetition of similar parts on each side of the central axis, and this bilateral symmetry extends to the ligaments, the muscles, the nerves, the blood-vessels, the lymphatics, and the organs or viscera by which animal and vegetable life is supported, the heart, the lungs, the liver, the kidneys, and the alimentary canal, &c. Some exceptions to this symmetry are more apparent than real. With the Skull are connected two arched bones, the Lower Jaw, the agent for masticating the food, and the Hyoid (or U shaped) bone, which supports the tongue and surrounds the upper part of the tube through which air is transmitted to the lungs. With the Thorax is connected on each side an osseous girdle composed of a flat bone called the Scapula or shoulder blade, which rests on the Ribs behind, and a long sinuously-curved bone, the Clavicle or collar-bone which forms an arch in front. Attached to this girdle is the upper limb composed of bones which are light and elegant, and so united as to admit of the greatest freedom of movement. With the Pelvis are connected the lower limbs, composed of bones remarkable for their size and strength, as well as mobility, and therefore specially adapted for their particular office of supporting the weight of the body during rest and progression.

(*a*) These Lectures are not given word for word as they were delivered, but contain the substance of several courses. They are designed specially for the use of students and as an *introduction* to the systematic study of human anatomy. One or two preliminary lectures delivered in previous years have been omitted, as it has been considered advisable to plunge at once *in medias res*. An Introductory Lecture was published in the Medical Press and Circular on January 13th and 20th, 1869.

(*a*) See Liddell and Scott's Greek Lexicon.

The Skull consists in the adult of twenty-two bones, eight of which form a covering for the Brain, the Brain-capsule or Cranium, whilst the remaining fourteen compose the Face. The small arched bone already mentioned, the Hyoid bone, might be reckoned as belonging to the skull, as it is connected with that part of the skeleton by ligaments, and these ligaments it is interesting to note are not unfrequently converted into bone as you may observe in the specimen on the table.

The Thorax consists of twelve pairs of long curved bones jointed to the vertebræ behind and ending in cartilages in front. The upper seven join a central bone called the Breast bone or Sternum, itself terminating below in a cartilage variable in size, shape, and direction, the Ensiform Cartilage.

Regarded as a whole the bony capsule of the thorax, completed as it is by the Intercostal Muscles and covered by soft structures, affords an efficient protection to two of the most important organs in the body, the Heart with the large blood-vessels springing from it, in the centre, and the Lungs at the side, whilst it is admirably adapted for the movements which are necessary in the process of breathing, the mobility of its segments admitting of its enlargement for the entrance of air into the lungs in inspiration and the elasticity of its osseo-cartilaginous hoops ensuring a resilient pressure sufficient in conjunction with the elasticity of the lungs themselves to expel the air from those organs in expiration.

The Pelvis is formed behind by the terminal bones of the Vertebral Column, the Sacrum and Coccyx, and at the sides and in front by two large bones, single in the adult, called the Innominate bones. Each of the Innominate bones consisted in early life of three distinct pieces united by cartilage, the Ilium, the Ischium, and the Pubes. Looked at as a whole we find the Pelvis presenting a marked contrast with the Thorax. The latter is a light and airy cage made for mobility, the former is a rigid bony ring made for strength, protection, and support. It encloses in both sexes organs connected with the functions of Micturition, Defæcation, and Generation. How admirably adapted is the female pelvis for the special part which it has to play in Gestation and Parturition, you may be able to gather from some remarks which I shall have to make in a subsequent lecture, and will more fully understand when you study the Obstetric Art under the guidance of the Physicians who lecture on the subject and demonstrate it at the Hospital.

As in all the Vertebrate Classes, the Human Skeleton is symmetrical—each lateral half is exactly alike in structure and arrangement. The Limbs are four in number, for it is a differential character of the Vertebrate Sub-kingdom that the limbs, when present, are never more than four in number. Absent the limbs may be, as in Serpents, or reduced to two they may be as in the Cetacea, but in no class of vertebrate animals can more than four be found.

Reckoning up the number of the bones we find at the lowest computation 206. In the Skull as already mentioned there are 22; in the Spinal Column of the adult there are 26; in the Thorax there are 25; in the Upper Limbs, including the Scapulæ and the Clavicles there are 64; 32 in each limb; in the Lower Limbs, including the Innominate bones, there are 62—31 in each Limb. Add to these the Hyoid bone and the small bones found in the Ear, and we obtain a total of 206.

Arranged in a tabular form they stand thus :—

Skull	22	This number may be considerably increased by reckoning separately the original elements of the adult bones and adding the sesamoid bones, &c.
Spine	26	
Ribs	24	
Sternum	1	
Os hyoides	1	
Upper limbs 32 × 2 =	64	
Lower limbs 31 × 2 =	62	
Bones of the ear 3 × 2 =	6	
	206	

It is desirable that we should commence the study of the bones with the Vertebral Column, for it is the centre around which the other parts are grouped; it is the part of the body which is first laid down in the embryo; it is the distinguishing feature of the great Sub-kingdom Vertebrata.

In the Vertebral or Spinal Column of the adult there are twenty-six bones, twenty-four true vertebræ, so called because they are separate and complete in all their parts, and two bones, the Sacrum and Coccyx, called false vertebræ, because composed of several vertebræ amalgamated and incomplete. As a whole, this column consists of two chief parts—in front a solid pillar or cylinder for transmitting the weight of the body and supporting the head; behind a canal enclosing and protecting an important portion of the central nervous system—the spinal cord. Now, just as the whole column consists of these two parts, a cylinder and a canal, so will each separate segment of it consist of a section of the solid cylinder and a section of this canal. The section of the cylinder is called the Body of the vertebra; it lies in front and springing from it behind is the rest of the wall of the canal which is called the Arch, while the actual section of the canal itself is called the Foramen or Hole. From the Arch spring certain projections called Processes, because they proceed from it, a projection from a bone being very generally termed in anatomy a Process. The term apophysis, derived from the Greek, has a similar meaning. A few words on each of the parts of the man vertebra.

The *Body*—more or less flattened at its two ends—more or less rounded on its outer surface, especially in the centre, expanded at its extremities, constricted in its waist, represents the shaft of one of the long bones. It is united to the bodies of the vertebræ above and below by an elastic structure called the intervertebral substance. The outer crust of the body of the vertebra is composed of hard firm bone, called compact bone. The interior is composed of an open network of fibres, called cancellous tissue. The Latin verb "cancello" is to make lattice-wise. Holes may be observed on the front surface of the compact tissue. Canals may be observed in transverse and vertical sections of the cancellous tissue. Large holes, often two large holes, sometimes one very large hole, may be observed on the hinder, or as we call it, the posterior surface of the body. These holes and canals are for the blood-vessels supplying the vertebra—the arteries and the veins. The arteries enter the vertebra from the spinal canal, a few small vessels passing in also in front. The veins which lie in the larger canals emerge from the larger holes behind, and terminate in the copious venous plexus which is found at the back of the bodies of the vertebræ within the vertebral canal.

The cancellous structure of the vertebra is more open in the centre than at the sides. The spaces are larger, and the thin plates bounding the spaces are more slender in the larger vertebræ, as in the lumbar compared with the dorsal, or as in the dorsal compared with the cervical. "Thus in the neck," to quote Professor Humphry's account of the cells of the cancellated tissue, "the septa are thick, and the bone is consequently dense; in the back they are larger, the septa are thinner, and the bone is consequently more spongy; in the loins they are still larger, the septa are still thinner, the vascular canals are much wider, and the bone is altogether very spongy." (Human Skeleton, p. 137.)

The *Arch* consists of two *Pedicles* and two *Laminæ*. The *Pedicles* are so called because they are more or less slim and rounded, like legs. Pediculus in Latin is the diminutive of pes—a foot. The *Laminæ* are so called because they are more or less flattened. In anatomy a thin plate of any substance may have the Latin term *lamina* applied to it.

The Pedicles spring from the upper part of the body, and often diverge to some extent from each other. Above and below each pedicle is a depression, or in other words, the pedicles are hollowed above and below, and these hollows are called the Notches—superior and inferior. There is therefore a superior and an inferior notch to each pedicle, four notches to each vertebra.

The Laminæ spring from the ends of the pedicles, and converge, forming a junction behind, and completing the Arch for the enclosure of the spinal cord.

From the point of junction of the Pedicle and Lamina on each side, an important spot, spring three Processes. One passes outwards, horizontally or transversely, the Transverse Process; one passes upwards, the superior Articular Process; one passes downwards, the inferior Articular Process.

From the point of junction of the two Laminæ passes backwards another process central and single—the Spinous Process. The articular processes are generally stout and stumpy; the transverse and spinous processes are longer, more cylindrical, and often ending in an enlargement, or nob—anatomically speaking, a tubercle.

Altogether then the parts of a human vertebra are eighteen, just double the number of parts of speech; a Body, two Pedicles and two Laminæ, forming the Arch and enclosing the Foramen, or Hole; four Notches, two superior, two inferior; and seven Processes, four Articular, two Transverse, one Spinous. The special uses of the bodies of the vertebræ are the support of the head and other parts of the organism, and the transmission of the weight of the body to the pelvis and lower limbs. The special uses of the arch are to afford protection to the spinal cord, and support to the processes which jut out from it. All the processes give attachment to numerous muscles chiefly placed in the back. By the articular processes the separate vertebræ are locked together, and their movements limited. By the transverse processes of the dorsal vertebræ the ribs are supported. The spinous processes not only afford leverage to the muscles of the back, but guard the vertebræ and spinal cord from injury, and forming together a marked projecting ridge have given the name of spine to the whole column. Lastly, the notches of adjacent vertebræ form, when the vertebræ are united together, large intervertebral apertures or foramina. Through these foramina emerge the nerves which come off from each side of the spinal cord to supply the muscles and the skin over the greater part of the body, and through these foramina pass the various bloodvessels which belong to the spinal cord and the vertebræ.

A lecture on the parts of a vertebra would scarcely be complete if it did not make some allusion to or give some account of what has been called a Typical or Ideal Vertebra. There is a certain set of Anatomists who are called Transcendental Anatomists, because, not resting at the knowledge which they have obtained by actual observation, they endeavour to transcend or go beyond the limits of experience, and to form conceptions of an ideal character out of the facts which they have acquired by means of the scalpel and the microscope. It is difficult to describe exactly the scope and object of a transcendental anatomist, but in some measure he has a soul akin to that of the poet, who "doth glance from heaven to earth, from earth to heaven, and as imagination bodies forth the forms of things unknown, turns them to shapes, and gives to airy nothing a local habitation and a name." (a) They seem to aim at discovering the primary ideas or conceptions which led to the creation of the various forms of particular objects. It is affirmed that there must have been an original pattern, by the modification of which in particular instances variety of form has been obtained. This original pattern, ideal as it is, is called in transcendental language an Archetype. In illustration and elucidation of these remarks let me take a vertebra. The transcendental anatomist collects the different kinds and forms of vertebræ and compares them together. He finds in some, parts and processes which are wanting in others. In the vertebra of a fish, for instance, he finds not one arch as in man, but two arches, one above and one below the body. Again, in the vertebræ of some of the mammalia lower than man (the hare and the dog for instance) he finds additional processes to those which are developed in a human vertebra. Taking all these peculiarities, he puts them together, and obtains what he calls an Ideal Vertebra—the Vertebral Archetype—the very original type and model by the modification of which were obtained the piscine, the leporine, the canine, the human, and indeed all the different vertebræ. To this archetypal vertebra he gives certain names which are deemed the proper scientific names of the parts. In the diagram here suspended you have the Ideal Vertebra represented.

This Ideal Vertebra is a symmetrical structure which consists of a central portion with the other parts so grouped around it, as to enclose four distinct canals, one in front, one behind, and one on each side. The central portion is called the Centrum or Body, and it is the most constant part of a vertebra. It may be present when all the other parts are absent, as in the caudal portion of the vertebral column forming the basis of the tail. In man we find the centrum alone in some of the pieces of the last segment of the spine—the coccyx. Behind or above the Centrum we find an Arch, as in man's vertebra, enclosing a canal for the spinal cord, and hence called the Neural Arch—the side pieces of the arch represented in man by the Pedicles and Laminæ are called the Neural Processes or Neurapoplyses, and springing from their junction is a process which juts backwards or upwards, called the Neural Spine, and corresponding to the Spinous Process in man. Below or in front of the Centrum is another Arch, intended to enclose a large bloodvessel, and hence called the Hœmal Arch, formed of the Hœmapophyses, which unite together and support the Hœmal Spine. The lateral canals are enclosed by two transverse processes springing from the centrum in front and behind, and called the Anterior Transverse Processes, or Parapophyses, and the Posterior Transverse Processes, or Diapophyses. Springing from a point between the transverse processes is another process resembling a Rib, and called the Pleurapophysis. The lateral foramina thus enclosed give passage to an artery, and correspond to the foramina in the human cervical vertebra for the transmission of the Vertebral Artery.

MEDICAL SOCIETY OF LONDON.

December 23, 1872.

Thos. Bryant, Esq., F.R.C.S., President, in the Chair.

Dr. **Brunton** showed a specimen illustrating

OSSIFICATION OF LONGITUDINAL SINUS AND MEMBRANE OF THE BRAIN,

there was also a slight patch of softening. The patient died of fatty degeneration of the heart. She was a woman, and was 27 years of age.

Prof. **Erasmus Wilson** said it would be interesting to know the use of the Pacchionian bodies. He could not understand the relation between diseases of those bodies and fatty degeneration of the heart.

Dr. **Wiltshire** thought it would be better to speak of such changes as Dr. Brunton found in the brain as calcification rather than ossification, seeing that there were no Haversian systems. He wished to ask whether the patient had borne children, and if so, how recently, and whether there was any disease of the coronary arteries of the heart.

Mr. **Streeter** would like to know how many times the patient had been pregnant. Rokitansky had shown there was an osteophytic deposit in the brain after every pregnancy.

Dr. **Brunton** had no intention of saying that degeneration of Pacchionian bodies was the cause of degeneration of the heart. The patient was delivered three weeks previously.

Prof. **Erasmus Wilson** had gathered from Dr. Brunton that the patient was a teetotaller, and he thought such a person was not to be looked upon as necessarily healthy, muscular substance was taken up but re-placed by inferior tissue owing to malnutrition.

Dr. **Brunton** also showed

A LAD, ÆT. 19, WHO WAS THE SUBJECT OF MORBUS CŒRULEUS,

he had blue lips, livid skin, occasional hæmoptysis, and ecchymosis, now and then he had palpitation.

The **President** related a case equally severe, which he thought illustrated the remarkable resistance of disease with which these patients were endowed. The patient, a young lady, æt. 22, had severe rheumatism with heart affection, from which she recovered perfectly, under the care of Dr. Herbert Davies.

Prof. **Wilson** said that reptiles were less obnoxious to inflammation than warmer blooded animals, and these persons partook somewhat of the character of such creatures as regarded their hearts. The nervous organisation of reptiles was also inferior.

Dr. **Crombie** showed

A NEW APPARATUS FOR THE SELF-ADMINISTRATION OF CHLOROFORM.

The **President** remarked that the apparatus was very like Dr. Junker's.

Mr. **Bell** did not think it was suited to operations.

Dr. **Farquharson** thought the self-administration of chloroform was not desirable without the presence of a skilled person.

(a) "Midsummer Night's Dream." Act V.—Scene i.

Mr. Henry Smith showed

A SPECIMEN ILLUSTRATING PRIMARY EXCISION OF THE ELBOW-JOINT FOR INJURY.

The arteries and nerves were not involved, but the whole joint was so injured that he performed primary excision. He also showed

A PORTION OF BONE REMOVED BY TREPHINING FROM THE SKULL OF A MAN INJURED BY A HATCHET.

After a period of quiescent delirium which was relieved by trephining, the man died. There had been bleeding from the ears, and at the *post-mortem* a fracture was found through the fibrous portion of the temporal bone. A small quantity of blood was found effused beneath the dura mater.

The President was glad to hear of the repetition of the operation of primary excision of the elbow joint for injury. He had lately seen a man upon whom the operation had been performed thirty years ago, by Mr. Cock, where an excellent arm was preserved to the patient. He approved of the operation. With respect to the second case, injury to the skull added little risk to the operation, while the brain remained uninjured.

Mr. Henry Smith did not think so lightly of these injuries.

Mr. Streeter wished to know how we could tell there was a fissure in the cases that recovered.

Prof. Wilson thought the hæmorrhage from the ear was some evidence.

Dr. Dowse related a case of fracture of the base of the skull in which there was hemiplegia, and in which recovery took place.

Prof. Wilson showed

TWO LOCKS OF HAIR, ONE WHITE AND ONE BLACK.

A lady, æt. 37, and pregnant, had a shock, after which all her hair fell off and she became bald for a year, then her hair came again but was quite white, and remained so three years, ultimately, it became dark again, and even blacker than before. The influence of the nervous system was well-known. Perhaps, in this case, the change was intensified by pregnancy in which condition the tissues were subject to important changes. It differed from cases of hereditary baldness. The influence of the nervous system was illustrated by jaundice occurring in three persons one after the other; the second and third from seeing the first.

The President asked whether the eyebrows and lashes were white, and was answered in the negative. How did Prof. Wilson account for the circumscription of the change to the hair of the scalp?

Prof. Wilson supposed the functions of the scalp were under more important nerves than other hairy parts of the body. The fifth was an important nerve and was more susceptible of influences. He mentioned a specimen in which the hair was brown and white in equal segments. It was inferred that the brown was grown in the day and the white in the night.

Mr. Nelson Hardy asked whether the lady wore artificial hair, as white hair grew beneath wigs.

Dr. Brunton asked what pathological change took place when the hair became grey in a night.

Mr. Spencer Watson was reminded of a case of a man whose hair had been white from a boy. He had a narrow escape from drowning and after that his hair soon became white.

Prof. Wilson was convinced of the possibility of hair turning white in a night. The sudden introduction of air into the hair was believed to be the explanation of the phenomenon. Whether the air got in from without, or was secreted, he did not know.

Mr. Hogg did not think the air theory satisfactorily explained the phenomenon.

Prof. Wilson said there was no doubt that the air bubbles were in the hair and they acted as a curtain and hid the pigment. They could be seen by the microscope any day.

Mr. Wm. Adams brought forward

TWO CASES ILLUSTRATING THE ADVANTAGES OF GALVANISM IN THE EARLY STAGES OF INFANTILE PARALYSIS.

Mr. Spencer Watson asked to what particular parts the galvanism was applied, whether to the spine, nerves, or muscles, which.

Mr. Wm. Adams answered by saying that galvanism was applied under water, both legs being put under water in separate vessels, and then one pole should be applied to each limb. After this each muscle should be separately galvanised. He agreed generally with Sir Benjamin Brodie's remarks that if recovery did not take place within six months, the case was almost hopeless.

The President still was of opinion that in some cases early galvanism was injurious. He had seen bad results from that practice and thought it should not be used under three or four months.

WEDNESDAY, JANUARY 15, 1873.

THE MEDICAL ASPECTS OF THE DEATH OF NAPOLEON III.

Last week when recording that Sir H. Thompson had performed lithotrity on the late Emperor Napoleon we mentioned our own reasons for feeling no surprise that such a procedure had been undertaken, and stated that we had long since been aware of the nature of the case.

On Thursday the patient died in an unexpected manner. He had passed a quiet night, had been carefully watched by his Medical advisers, and it had been decided to operate again the same day at noon. But before that hour death had precluded all further attempt to relieve. So suddenly had the patient sunk that embolism was naturally suspected, and it is unquestionably to the surprise of many Medical men that the *post-mortem* examination did not reveal such a condition. Death seems to have occurred from an unexpected failure of the heart's action, and cannot be traced to the operation itself, which was evidently accomplished with the utmost skill and success. It is to be remembered that the patient was advanced in years, and that his disease had lasted a long time, while his life had been one of continual wear and tear.

It is undeniable that measures for his relief were postponed to the uttermost, and no one will now question the accuracy of the information we last week put forward. This has, indeed, been more than confirmed by Professor See, of Paris, who, according to our able contemporary the *Union Médicale*, says that on July the 1st, 1870, the Emperor Napoleon feeling very ill, a consultation took place between Drs. Nélaton, Ricord, Fauvel, Corvisard, and See. Their diagnosis was that of stone, and an immediate operation was recommended. Dr. Conneau was charged to communicate this opinion to the Empress Eugenie. But from political considerations the matter was hushed up, the Empress was not told anything on the subject, and the disease was allowed to go on augmenting for two years and a half. The *Union Médicale* adds, that if the truth had been told to the Empress, the probability is that the Emperor would have been cured, and that France would have been spared the late war.

It is obvious that this statement only confirms more circumstantially what we had previously put forth, though the fatal end of the case deprives it of a portion of its Medical interest.

From this and other facts it seems tolerably clear that there never was any difficulty as to diagnosis. The usual attendants of the Emperor, and all the eminent members of the French faculty who were consulted were perfectly acquainted with the nature of the case and the indications for treatment. There is, therefore, no pretence whatever for extolling the skill of our English brethren, who had only to satisfy themselves of the accuracy of their French compeers in a case in which error would have been inexcusable. The only point is that the delay that took place, and which rendered lithotrity less promising, was apparently entirely the choice of the patient, who fully understood the conditions of the case.

When at length lithotrity was tried it was carried out, as we have said, with success, and this is proved by the official report of the autopsy made by Dr. Burdon Sanderson in the presence of those who were in attendance, and which is as follows:—

"The most important result of the examination was that the kidneys were found to be involved in the inflammatory effects produced by the irritation of the vesical calculus (which must have been in the bladder several years) to a degree which was not suspected; and if it had been supposed, could not have been ascertained. The disease of the kidneys was of two kinds; there was, on the one hand, dilatation of both ureters and of the pelves of the kidneys; on the left the dilatation was excessive, and had given rise to atrophy of the glandular substance of the organ. On the other, there was subacute inflammation of the uriniferous tubes, which was of more recent origin. The parts in the neighbourhood of the bladder were in a healthy state; the mucous membrane of the bladder and prostatic urethra exhibited signs of sub-acute inflammation, but not the slightest indication of injury. In the interior of the bladder was found a part of a calculus, the form of which indicated that half had been removed. Besides this, there were two or three extremely small fragments, none of them larger than a hemp-seed. This half calculus weighed about three-quarters of an ounce, and measured 1¼ by 15-16th of an inch. There was no disease of the heart nor of any other organ, excepting of the kidneys. The brain and its membranes were in a perfectly natural state. The blood was generally liquid, and contained only a very few small clots. No trace of obstruction by coagula could be found either in the venous system, in the heart, or in the pulmonary artery. Death took place by failure of the circulation, and was attributed to the general constitutional state of the patient. The disease of the kidneys—of which this state was the expression—was of such a nature, and so advanced, that it would in any case have shortly determined a fatal result.

"Signed by all present.

"J. Burdon Sanderson, M.D.
"Dr. Conneau.
"Dr. Le Baron Corvisart.
"Henry Thompson.
"J. T. Clover.
"John Foster.

"Camden Place, Chislehurst, Jan. 10, 1873, 6.30 p.m."

Sir William Gull records a separate opinion on one point only, viz., the origin of the calculus, in the following terms:—

"I desire to express the opinion that the phosphate of lime calculus which formed the nucleus of the mass was the result of the prior cystitis (catarrhus vesicæ), and not the cause of it. This nucleus was of uncertain duration, and may even have been more recent than supposed in the appended report. However this may be, it was encrusted by two distinct and recent formations of crystalline phosphate. The inner incrustation around the amorphous phosphate of lime was dense, and separated from the outer incrustation by a lesser cellular but crystalline deposit of triple phosphate. It seems, to my judgment, more in accordance with clinical experience to regard the cystitis, as the prior lesion, and that this, by extension, as is common in such cases, affected subsequently the ureters and pelvis of the kidneys. No doubt, in the later stages of the malady the calculus, by its formation and increase, was an augmenting cause of the lesions.

"The other facts and statements I entirely endorse.

"William W. Gull, M.D.

"January 10th, 1873."

There are but two points on which we propose to comment. In the first place, the dissent recorded by Sir W. Gull will not command so much attention now it is shown that the Emperor had actually suffered from the symptoms of stone for years. The conclusion of the report is strictly "in accordance with clinical experience" generally, and what is far more to the point, with the *clinical history of the case itself.* The general question raised may be left to those pathologists who have best opportunities of investigation. The other question that will suggest itself to most surgeons is, would lithotomy have been more advisable? The size of the stone certainly suggests that the case, as presented to the surgeons, was one calling for anxious consideration as to the propriety of cutting. For be it observed the advanced disease of the kidneys was not suspected. Had it been known to have existed it might have been determined to abstain from all interference, merely employing palliatives. But then the further question returns of the duration of that disease. Had it been determined to attempt a cure when the stone was first diagnosed would it have been in time to select either operation, and in that case which would have been preferable? The answer of course involves the whole subject of the relative value and position of the two operations, and will probably be answered differently by different operators.

◆

ANÆSTHETICS CONSIDERED IN RELATION TO THE DEATH OF THE LATE EMPEROR.

By the decease of the ex-Emperor, amongst other topics of interest in Medical circles, that of the influence of chloroform in hastening his death in any way has been discussed. The following extract from one of our leading daily papers testifies to the disquieted condition of the public mind on the great question of the use of anæsthetics, and more particularly as to the danger, whether immediate or remote, of chloroform :—

> "There is much talk among the newly-arrived visitors from Paris respecting the immediate cause of the Emperor's death. The fact that the Emperor was at an age when lithotrity is generally performed with success, and that two operations were not attended with more than usually severe symptoms, seems to have raised some doubt in their minds as to the part the application of chloroform may have had in the unexpected collapse."

How far the administration of chloroform could have aided in the sudden cessation of so remarkable a life may be a matter of speculation and of further discussion in Medical circles. Was such a condition as was shown in *post-mortem* examination one in which chloroform, with its known influence on the condition of the blood, should have been given? or did the depressing effect, admittedly resulting from chloroform inhalation, impress a system already debilitated by disease and anxieties? These may be, and are, doubtless, matters at the present crisis in the discussion of anæsthetics which are of intense interest. Ether, which has lately come to the front with such vigour that it is likely to outrun its favourite brother chloroform, presents claims which, in view of the age and condition of the late august patient, cannot be overlooked. Its stimulating effect upon the heart, which in this case so suddenly flagged, is beyond question. All investigations and observations have confirmed this view. The proofs brought forward by sphygmographic writings by Dr. Morgan, in a series of papers in the pages of this journal, amply testify its power. The remarkable effect on the blood which, in amputations under ether, flows of a bright arterial hue, in contrast to the dark appearance when chloroform is used, speaks volumes for its safety, while the results of statistics place its superiority beyond discussion. Since June last we are aware that in Dublin numbers of cases have been etherized, both in hospital and private practice, with the happiest result. During the last week a dignitary of the Roman Catholic Church, with whom, from his condition of health, &c., chloroform would have been inadmissible, was *etherized*, and underwent the operation of lithotomy with the happiest result. Another case in private practice, of an elderly gentleman, was also lithotomised under the influence of ether with the best results. In our last issue we quoted a case of lithotomy of a boy at the Meath Hospital, also most successfully operated on, under the influence of ether. It will be gratifying to the Profession to know that the College of Surgeons of Ireland has taken steps to aid in the determination of the relative value of these anæsthetics. The Ether and Chloroform Committee appointed by the College and Surgical Society of Ireland has now completed a scheme for hospital observation throughout Dublin, and we shall from time to time keep our readers *au courant* with the results.

◆

RELAPSING FEVER.

The outbreak of relapsing fever in London seems likely to prove more serious than was at first thought likely. It was natural in a season of unusually low mortality to hope that the appearance of this fever on the Registrar-General's books was only for a single week, and due to causes that, if not understood, were at least not about to give rise to much further mortality. The fact has, however, proved otherwise. We have already heard of the dreaded disease in Nottingham, Manchester, and other parts, besides the area of the Metropolis in which it first appeared this time. The country is certainly threatened with another invasion of the disease, and it becomes Medical men to be on the alert. We are glad that the Medical Department of the Local Government Board is awake, and has already issued the following directions :—

1. Relapsing fever is in a very high degree communicable from sick to healthy. The greatest personal predisposition to the disease is given by states of poverty and privation : so much so that the disease is often known by the name of famine-fever. The more confined the atmosphere in which sick and healthy are together, the more certain is the disease to be communicated.

2. Relapsing fever is eminently a disease which cannot safely be treated in the houses of the poor; for in them, crowded and ill-ventilated as they generally are, and with inmates often insufficiently nourished, there must be every likelihood that the infection will spread. It is essential that under such circumstances the sick should at once be removed from amid the healthy. Ample hospital accommodation is therefore an indispensable condition for limiting the extension of the disease.

3. Where relapsing fever has attacked, and when all its acute symptoms are past, the sufferers remain for a while extremely weak, requiring that food and restoratives should be liberally supplied them; in default of which, the feebleness left by the disease may often be of indefinite duration. This is the more important, because, where relapsing fever becomes epidemic, typhus often accompanies or follows it; and persons whom the relapsing fever has weakened not unfrequently fall victims to typhus.

4. At present (as in all times when epidemic disease is prevalent or threatening) it is particularly important that powers conferred by the Nuisances Removal and other general Sanitary Acts should be well exercised by those in whom they are vested. Very detailed district-inspection is most necessary. Everything practicable should be done, especially in all poorer parts of each district, to promote cleanliness of and about dwellings. The washing and lime-whiting of uncleanly premises, especially of such as are densely occupied, should be pressed with all practicable dispatch. It is essential that overcrowding should, as far as possible, be prevented, and proper ventilation be enforced; and in these respects common lodging-houses, and houses which are sub-let in several small holdings, will require particular attention. Great vigilance must be used with a view to the discovery of first cases of relapsing fever in such houses; and frequent inquiry should be made as to the sorts of illness prevailing among the poor. The attention of Authorities is invited to the powers conferred on them by various sections of the Sanitary Act of 1866, with reference to infectious disease; especially to the powers conferred for purposes of disinfection, and for the conveyance of sick persons, and for the separation of the sick from the healthy.

5. Relapsing fever, as described in Medical text-books, has the following characters. The patient becomes suddenly ill with shiverings, headache, heat of skin, prostration, and generally vomiting. To these symptoms are usually added more or less yellowness of skin, and severe general pains resembling those of rheumatism. After from five to seven days, the symptoms abruptly cease. For a week the patient feels well, and has his ordinary appetite, his natural temperature, and a pulse often even slower than in health. On or about the fourteenth day from the commencement of the original attack, relapse takes place, with a sudden paroxysm of fever similar to the first. The duration of the stage of relapse is commonly three days. Second, or even several, relapses sometimes occur; and as above stated, convalescence is usually protracted.

◆

THE REPRESENTATION OF THE IRISH COLLEGE OF SURGEONS.

It may be conceived that we look with much interest for the opinion of the law advisers of the College as to the legality of Mr. Hargrave's present tenancy, because, having raised the question, we are bound to our readers and the Fellows of the College to obtain, if possible, a definite reply to it.

It is, in truth, by no means to the credit of the Council that the capacity of Mr. Hargrave to act as parliamentary spokesman of the College should be tried on such an issue, or that it should be left to the MEDICAL PRESS AND CIRCULAR to throw down the glove for such an inquiry.

The Council has indeed been very little Mr. Hargrave's friend in subjecting him to the issue of a legal inquiry which was called into existence by their indecision and their apparent indisposition to sacrifice personal sentiment to Collegiate necessities. While we have not flinched—and will not again—from speaking loudly and in unequivocal terms respecting Mr. Hargrave's continuance in office, and the undignified hesitancy of the Council, we have at no time forgotten the position in the affections of the College which Mr. Hargrave's long services and unsullied loyalty entitle him to. Our correspondent of last week, "A Fellow of 1844," has done him the least justice in describing him as "True Blue," and we heartily join with him in acknowledging that Mr. Hargrave has never swerved in his devotion to the College. Advanced age or impaired health cannot shake that feeling, but they must interfere with, and it is our duty to say have made that devotion unavailing, and have rendered the former representative totally and undeniably incapable of doing justice to the interests of the College. The guardians of those interests—the Council—should have been the first to make Mr. Hargrave aware of that fact, in the most considerate manner which might have suggested itself, and they have one and all shrunk from the discharge of a plain duty and a simple act of kindness, and thrown it upon the Fellows of the College and the public press to speak the words in harsher phrase. Even to this day it is possible—so far as any sign has been made by them—that Mr. Hargrave may be under the impression that the Council has unbounded confidence in his powers. We are well aware that the Council—we might almost say every individual member of it—recognises the impossibility of Mr. Hargrave ever again acting in the College interest, and yet there is none to speak the word which shall convey to Mr. Hargrave an unmistakable impression of the kindly but firm feeling of the Council. Had such an intimation been conveyed to Mr. Hargrave on the part of the Council we cannot but believe that his self-esteem and his regard for the College would have induced him to retire from the false position in which the reticence of the Council has left him.

THE APPROACHING MEETING OF THE MEDICAL COUNCIL—THE IRISH CONJOINT EXAMINATION.

As we announced last week, the Executive Committee of the Medical Council meets this day, and the date of the meeting of the General Council will be then decided. That question will be determined in the greatest degree by the requirements of the scheme for a Conjoint Examination for Ireland, and as, we believe, the Irish licensing bodies who have taken part in that scheme are unanimous in desiring that it shall be brought into operation at once, we anticipate that the meeting of the Council will take place early in February.

The party who are active in the endeavour to delay or defeat any attempt at the self-reform of the licensing bodies, and who desire that the Government shall be compelled to deal with the subject of Medical education in a revolutionary spirit—Sir Dominic Corrigan, as representative of the Queen's University in Ireland, being the chief exponent of that view—are industriously circulating the statement that there is neither necessity for nor probability of a meeting of the Council or of any move in Parliament.

In pursuit of this policy an effort was made by Sir Dominic Corrigan last week in the College of Physicians to lay on the shelf the Irish Conjoint Scheme, and defer indefinitely any action upon it; but we are glad to learn that that subtle move was defeated by a large majority, and the endorsement of the College was accordingly put to the scheme by which it was, so far as the co-operating bodies are concerned, perfected.

Since then the same party has devoted its ingenuity to a "waiting game," and is exercising its influence to prove that there is no necessity for hurry, and that the Medical Council may as well meet in July or August, when Parliament is rising, as at any other time. If we are to believe the latest declarations of the Government on the subject, and to judge from the opinions of those who are usually well informed in such matters, we should say that if the Executive Committee be induced to listen to this statement and postpone the meeting of the Council, the much-needed reform may probably be settled without its intervention. In a letter addressed within the last month by the London Apothecaries' Company to the President of the Council, it was stated that "the Apothecaries' Company had been informed by Mr. Simon on behalf of the Lord President, that an application had been made to the Government with reference to a general measure, having for its object to enable the Medical colleges and bodies to agree to a conjoint scheme of Medical examinations, and that the subject was then under consideration.

"Mr. Simon, on behalf of the Lord President, further suggested that should such a measure be introduced it would probably be unnecessary for one to be brought in solely referring to the Society of Apothecaries."

It is plainly most improbable that the Government would put a stop to the progress of any licensing body unless a serious and well considered intention existed to make the matter a Government question, which, indeed, Mr. Forster has already said he is "most anxious" to do. Whether or not Parliamentary intervention be expected, it would be most unjust to the Irish licensing bodies, who have sacrificed much of their individual interests for the purpose of complying with the orders of the Council, and effecting a substantial and urgent reform, to treat their scheme with coldness, and force them to defer the setting of their house in order until such time as the Scotch purlieus shall be swept clean before the besom of Mr. Gladstone.

With the exception of the Queen's University, the Irish bodies have certainly deserved credit for their anxiety to initiate a change which shall be no sham. They have unhesitatingly yielded up privileges and income for the sake of such an object, and it would be unfair and improper if, to please the Scotch bodies or Sir Dominic Corrigan, the Medical Council should defer the time when the result may be achieved.

The *Medical Times and Gazette* joins us in urging an early assembly of the Council, and we have to express the hope that the mistake of last and former years will not be repeated by the calling together of that body in the dog-days to play out with a laboured pretence of energy a vapid afterpiece after the chief actors and the best part of the audience are gone home or to sleep.

Notes on Current Topics.

Death from an Operation on the Larynx.

Professional and lay circles in Vienna have been in rather a state of excitement owing to a most unfortunate occurrence in one of the hospitals in that city. A young woman, named Eliz. Trak, æt. 22, suffered from a tumour, diagnosed by the aid of the laryngoscope, to extend from the right side of the cricoid cartilage into the interior of the trachea. She attended the Poliklinik, and an operation was decided on.

On Dec. 23rd, Dr. Coen introduced an instrument provided with a syringe, and injected some ferr. sesquichl. into the tumour. Unfortunately, some of the fluid escaped on to the neighbouring parts, causing such severe spasm of the glottis that death instantaneously resulted. Laryngotomy, quickly performed, was of no service.

The *post-mortem* examination was made by Rokitansky. The most notable results were as follows :—Heart contracted, with fluid blood in its cavities; lungs inflated, partly œdematous; fluid blood in the trachea and large bronchi; two small wounds, caused by the injection, in the posterior membranous wall of trachea; two tumours, gelatinous in appearance, one on the anterior wall of the trachea, the other situated on the post extremity of the first ring of the trachea, roundish, pale, about five lines in diameter, and almost filling up the cavity of the trachea, immediately below the larynx. The mucous membrane on and near the tumour of a dirty yellow colour. The tumours were pronounced to be sarcomatous. The proceedings were all pronounced legally justifiable, and the operators free from blame. The *Allg. Wien. Med. Zeit.* remarks it is of the first importance that proper assistance be at hand in such cases.

Privileges of French Midwives.

After a long and warm discussion, the Paris Academie de Médicine has pronounced in favour of midwives being privileged to purchase, and employ ergot in their practice. Among the disputants, M. Toggiale warmly opposed the permission, whilst Tardieu took a different view, still considering ergot should be classed among poisons.

Quinine in Coffee.

The administration of sulphate of quinine in coffee, though an agreeable mode is, says M. Briquet (*Mouvment Médical*) a very bad one. For quinine combines with the tannin, in an infusion of tea or coffee, forming thus an almost insoluble tannate of quinine.

Dr. Louis Fleury.

We learn from *Le Mouvement Médical* that Dr. Fleury died on Dec. 14th, in the sixty-third year of his age. He was followed to the tomb by Drs. Aubartin, Brougniart, Bourneirlb, Kéller, and Krauss, of Vienna, and a short farewell was spoken over the grave by Dr. Aubartin, who spoke of him as the practitioner of scientific hydropathy.

Galvano-Cautery in Surgery.

Dr. Tripier (*Mouvement Médical*, Dec 21st) says the first trial of galvano-caustic is due to Faerè Palaprat, who was followed by Recamier and Pravaz, Marshall. Amussat used it in ranula, tumour, and varicocele; and Favignot perforated the crystallised lens and performed iridectomy by means of it. Seré, in 1860, devised a galvano-caustic knife, which is a loop of platinum in the form of a blade divided into two symmetrical halves. By the passage of a very powerful current this blade can be heated to 1,500 degrees. Platinum being a soft metal, does not cut when cold; but, when heated to a high degree, it acts as an excellent cutting instrument. The most useful application of this plan was made by M. Verneuil in tracheotomy.

Addison's Disease.

Dr. Bucquoy (*Mouvement Médical*, Dec. 21st) relates a case of a young girl, æt. 19, who had suffered from phthisis for eighteen months. Two days before she entered hospital there was continued vomiting with convulsions. On investigation there was noticed tuberculisation of the lungs and peritoneum, and besides this, a bronze colour of the skin of the face, neck, and axillæ. The patient soon succumbed, and at the autopsy, besides the tubercular lesions of the lungs and mesenteric glands, the supra-renal capsule of the right side was found to be hypertrophied to the size of a large chestnut and undergoing cheesy degeneration.

Syphilitic Urethral Discharges.

On January 20th, Dr. Henry Lee gave the first of the Lettsomian Lectures, entitled "Syphilitic Discharge," at the Medical Society of London. The lecturer defined clearly the fallacies into which John Hunter and M. Ricord had fallen, and insisted upon the following points : That an infecting primary sore in the urethra may cause, when uncomplicated, a discharge like arrowroot and water, without congestion of the urethral orifice; that a secondary syphilitic urethritis produces a purulent discharge; that purulent or serous secondary discharges may communicate syphilis; that inoculation with healthy pus will produce a pustule in a syphilitic subject. Mr. Lee said he had never known a primary sore occur further than half-an-inch from the orifice, and he could believe that such a sore would be caused only by the introduction of a contaminated instrument or other foreign body.

Another Successful Case of Nussbaum's Operation.

The *Allgemein. Wiener Med. Zeit.*, for December 31st, contains a most important case of elevation and stretching of the N. Sciaticus by Dr. Patauban. The patient had suffered for three years from severe left side sciatica, and had been treated by a number of physicians without any success in preventing the return of the attacks, especially in the cold months. Injections of morphia had been employed, but as is too often the case, with decreasing success.

The patient at length began to experience a feeling of insecurity in walking, of elongation of the lower extremity, exhaustion, and extraordinary sleeplessness. The injections of morphia still alleviated the pain, but unfortunately produced other objectionable results, dyspepsia, melancholy, and their effects. As the patient willingly consented it was determined to try the bold operation so successfully performed by Prof. Nussbaum. The painful points were, at exit of N. Sciaticus from the pelvis, a point on the spina iliaca post. sup., the spinous process of the fifth lumbar vertebra, and a fibular point. The nerve was laid bare by a deep incision, and dissected out from its connections with the MM. Gemelli, and the involved tendon of the m. obturat. int. and the quadrat femur, and isolated so that it could be moved in every direction. The plexiform roots of the nerve were next carefully separated from the superposed vessels, chiefly veins (ven. glut. sup. et nif., ven. sciatic. et pudend. int.), and from the periosteum, M. pyriformis. The neurilemma was obviously thickened. The nerve, thus isolated, as well as the intrapelvic roots, were then drawn and stretched to the fullest extent. From the moment of awakening from the narcosis, the specific sciatic pains disappeared and only the burning traumatic pain was felt. Suppuration continued for five weeks; the fibular point continued sensitive for some weeks; the patient rapidly recovered strength; the sleeplessnes being the last symptom to yield. An obstinate eczema broke out first around the cicatrix and then at different points of the leg, lasting two months. Motion, nutrition, and sensation remained unimpaired in the limb, but from time to time slight, passing pains were felt along the fibula and on the maleolus internus.

Royal Free Hospital.

At a quarterly meeting of the Committee of the Royal Free Hospital, held last week, Mr. Thomas Wakley, F.R.C.S., and Dr. Alexander Marsden, F.R.C.S.E., were unanimously, on the recommendation of the Medical staff, appointed consultin g-surgeons, in recognition of their long and highly valued services.

Small-Pox in Bavaria.

For the last ten years, small-pox has been more or less severely present in Upper Bavaria. It is now nearly extinct, and Dr. Wibmer gives a very useful *resumé* of the outbreak from official sources. For several years only a few sporadic cases had occurred; so much so, that in 1861-2, not a single death had occurred in Munich, and in 1863, only two. In 1864 an epidemic suddenly broke out. The cause most probably was importation, as several neighbouring countries were affected at the time, viz., Austria, Wurtemburg, Saxony, Prussia, and France. But in addition, there seems to have prevailed in Europe a special *constitutio epidemica*, epidemics raging in many countries, and originating in some places without any apparent source of infection. The first case of epidemic outbreak in Bavaria, occurred in February, 1864, at Tegernsee and Gmund, and was distinctly traced to a travelling dealer from Hungary. The epidemic lasted till July, and produced 47 cases, with seven deaths. In April of that year, epidemics occurred in several districts, including Munich, where it was introduced by means of a paper manufactory, through the medium of rags imported from Leipzic. This is absolutely proved by the fact, that about a dozen female *employées*, whose duty it was to sort the rags, took the disease. In the course of 1864-5, almost every district, in this part of the country was affected. In these two years 383 cases, with 35 deaths occurred in Upper Bavaria; in Munich alone, 82 cases with 2 deaths. In 1865-6, the epidemic became still more severe, and in Upper Bavaria there occurred, 1,346 cases with 69 deaths; in Munich, 746 cases with 25 deaths (*a*).

There occurred in Upper Bavaria, during—

1867	Cases	3,767	Deaths	267
1868	„	1,609	„	113
1869	„	457	„	34

In Munich—

1867	Cases	1,139	Deaths	66
1868	„	452	„	13
1869	„	77	„	3

In 1870, the disease had greatly diminished, but the return of the troops from France, and the arrival of French prisoners, spread it once more, so that in Munich alone, 7 deaths occurred during November and December. But 1871 showed a vast increase in the disease. 5,658 cases occurred in Upper Bavaria, with 832 deaths; the capital alone contributing to this total 1,471 cases, and 150 deaths. In 1872 the disease began to wane, and last September, only 15 cases, with 2 deaths occurred in Upper Bavaria; in Munich, 5 cases and *one death*, and this of an unvaccinated child.

In the ten years, 1862-1871, there were in all 14,473 cases in Upper Bavaria; in Munich, 4,314, (including modified and unmodified); It is, however, useless to strike an average, so variable was the distribution in different years, *e.g.*

Munich in	1862	Cases	7
„	1871	„	1,471

In Upper Bavaria, 1,544 deaths resulted from small-pox in these ten years. The proportion of deaths to cases was

In Upper Bavaria	10·66	per cent.
In Munich	6·65	„

The proportion of cases and deaths among vaccinated and unvaccinated was as follows:—758 (5·23 per cent.) of all the cases were unvaccinated. But among these 758 unvaccinated cases, 380 died, a mortality of 52·77 per cent.; whereas only 8·67 per cent. of the vaccinated cases died.

We have here another most remarkable instance of the great value of vaccination, in preventing fatal results from small-pox.

Of re-vaccinated cases	409 occurred.
Of these died „	24, or 5·86 per cent.

But it must be noted, that the success of the re-vaccinations has not been stated, and in most cases, re-vaccination had not been resorted to until too late.

Darwinism.

This subject was last week brought before the Victoria Philosophical Institute, by Dr. C. R. Bree, in a paper entitled "Darwinism and its Effects upon Religious Thought." Having defined these, he proceeded to show that the theories held by Mr. Darwin and his school, if argued out to their logical conclusions, were actually subversive of belief in Divine revelation. Many quotations from various authors were given. We quote three, one from Mr.

(*a*) Fuller details will be found in an important paper by Dr. Wibmer, in the *Arztlicher Intell. Blatt.*

Herbert Spencer :—"Every kind of being is conceived as a product of modifications wrought by insensible gradations on a pre-existing kind of being; and this holds as fully of the supposed 'commencement of organic life' as of all subsequent developments of organic life. It is no more needful to suppose an 'absolute commencement of organic life,' or a 'first organism,' than it is needful to suppose an absolute commencement of social life and a first social organism." And the other from Mr Darwin, in his "Descent of Man" (vol. i., pp. 66-7), about the probability of religion having its origin in dreams. "It is probable, as Mr. Tyler has clearly shown, that dreams may have first given rise to the notion of spirits," and "the belief in spiritual agencies would easily pass into the belief in the existence of one or more gods." And so according to Mr. Darwin's views, was religion "evolved." And a third from *Nature*, July 11, 1872. In a recent review of a work called the "Martyrdom of Man," we are told that the author, after working out the evolution of animal and human faculties, goes on to "urge all enlightened men to take part in the great work of demolishing one of those institutions, which, once the highest attainable, has now become injurious. Christianity must be destroyed." And he concludes his work in these words :—"But a season of mental anguish is at hand, and through this we must pass in order that our prosperity may rise. The soul must be sacrificed, the hope in mmortality must die. A sweet and charming illusion must be taken from the human race, as youth and beauty vanish never to return." Dr. Bree then called attention to the fact that, according to the theory of evolution, "a primitive speck of matter came into being, evolved from non-living matter by the agency of physical forces." Professor Huxley had called this the basis of life, that such pecks of living matter have given origin to all plants or animals; but Dr. Bree held that such a theory, even if true, did not go back far enough to explain the theory of all creation. After referring to the inconclusiveness of some, and the want of evidence for many other theories advanced by the Darwinian school, he urged that it was not the part of true science to attack religion, as was so often done, but rather patiently to practically pursue its course.

After Dr. Bree's paper was concluded, a discussion took place, in which Dr. Irons held that truth could never contradict itself, and hence there could never be any real antagonism between science and revelation. Admiral Halsted urged the importance of thorough inquiry. Dr. Fraser and Mr. I. T. Pritchard also spoke. Captain F. Petrie, referring to a remark made by a previous speaker, stated that the results of the experiments and researches of Professor Huxley and other leading scientific men, had as yet proved that though it was comparatively easy to classify animal creation, yet man held his place superior to the rest, and refused to "fit in" anywhere, and it was acknowledged that there was an immeasurable gulf between him, with all his attributes, and the rest of animal creation. Dr. Bree having replied, the meeting was adjourned.

Relation of Bad Smells to Disease.

In reference to a paragraph entitled "Needless Panic about Sewers," in the *Pacific Med. and Surg. Journal*, the New York correspondent of that periodical—the one who hates tobacco—takes up the matter with his usual vim, as followeth ;—

"Needless panic about sewers" is too positive for an obscure case. Open to argument, agreed. But you *don't know enough* to justify a dogmatic statement. Those fellows who worked in the sewers, didn't *sleep* in 'em. Men at work are always perspiring—*throwing off*, and therefore impervious to attack, in a general way. Arsenic diggers live long in mines, and eat arsenic. That don't prove that arsenic or its fumes won't kill people—does it? In some states of the atmosphere, even the little waste holes in our chamber basins, let up such a horrid stench that the room is intolerable. I have frequently cured, or stopped it, by pasting paper over them. Are not people made sick with the smoke of tobacco? What *is* stench? Who knows? Don't sewers give out a malarious vapour? In southern Indiana, people don't go out after sundown in summer, because ague follows *sure*. What's that? I would rather risk advocacy of the poisonous or deleterious character of all foul odours *à priori*, than the other side. Science and purity must accord here, I think. Some people get sick with the odour of apples. The "rose fever" or "hay fever" is quite common—comes on with some on the 28th day of July, and never fails on *that day*. Dr. Mason, scientific man near me, has the hay fever now, which, however bad, disappears as soon as he gets on the water in a ferry boat, and returns when he touches the land. I have no doubt that there is a specific poison to many lungs in the exhalations of our sewers—quite independent of the mere displacement of wholesome air. Anyhow, it strikes me that the Journal commits itself in an unscientific manner. Some big landlord of a sewer district has paid a doctor for a piece of special evidence, which, to my mind, proves nothing. I believe it is the theory of all our best physicians here, that all putrid exhalations are unwholesome *in*halations and therefore in degree poisonous. The same argument suggested by the Journal would prove tobacco and rum innocuous—or, at least, it squints so, or it seems to squint so, or it seems to seem to squint that way.

Mercurius Redivivus.

The editor of the *Pacific Med. and Surg. Journal* thinks there is a reaction in favour of mercury. He says: In fact, men are simply returning to their senses, and learning what they should not have forgotten, that the abuse of a potent agent is no argument for its entire proscription from medicinal use. The preparations of mercury have a peculiar action on the bodily organs, not exercised by any other agent. That lives are frequently sacrificed to the prejudice against mercury we have no doubt. It has been our province to witness more than one case of disease ending in death, which we felt confident would have been cured by the "old mercurial doctor." That the metal was used lavishly and needlessly in former times we do not doubt. But that it ever inflicted a tenth part of the evils on society that have been charged on it, we do not believe. It is well, however, that it took its proper place in our list of therapeutic agents—to be administered with discretion, keeping in view all possible evils that may result from it, and employing it only when enlightened judgment points to proper occasions.

The managers of the Edinburgh Infirmary have announced that they intend to cut down their fever beds from 150 to 36.

Still Earlier Intelligence.

Editors of the common sort may be content if they can dish up the record of events the instant they occur. It is reserved for the *dii majores* amongst editors, the Phaetons who think they can steer two chariots and upset neither, to publish news in advance of its occurrence. We read last Wednesday in the Dublin daily papers that the *Medical Record* had opened its prophetic mouth to describe the method and cause of the Emperor's death. Unfeeling hoax on the unsuspecting newspaper! The *Medical Record* had done nothing of the sort. The Emperor's death had occurred long after the *rechauffé* of the *British Medical Journal* had passed the printing machine. Not a word of the oracular pronouncement appeared in that journal, but the sharp editor, thinking (as indeed he easily might) that no one would notice the absence of the announcement, supplies it after date to the gaping newsmonger, and thus gets credit for a greater endowment in smartness than veracity.

University of London.

The office of assistant registrar in the University of London having become vacant by the resignation of Dr. Hirst, the Senate are about to appoint a successor, who will also be charged with the duties of librarian. The salary of the assistant-registrar and librarian will be £500 a year. His whole time must be devoted to the business of the University. Further information may be obtained by application to the registrar. Candidates must not be less than twenty-five or exceed forty-five years.

The Faculté at Paris has elected M. Paul Lorain to the Chair of History of Medicine, by a large majority over M. Bouchut.

Dr. Francis R. Hogg, R.H.A., a frequent contributor to our journal, has been presented with a valuable testimonial and address by friends and patients at Woolwich on his departure for India.

The library of the late Dr. John Blyth, Professor of Chemistry in Queen's College, Cork, will be disposed of by auction at the rooms of Messrs. Puttick and Simpson, in London this (Wednesday) afternoon.

Prof. Albini, of Naples, has successfully employed transfusion of the blood of a lamb in a case of anæmia.

A competitive examination of candidates for admission into the Medical service of the Royal Navy, will take place at the University of London, on Monday, February 17th, 1873, and following days, at ten o'clock.

The American Medical Editors' Association offers a prize of $100 for an essay, to be awarded in May, 1873, "On the Pathology and Treatment of Diseases of the Ovaries." The subject of the prize for 1874 is, "At what stages of Pulmonary Tuberculosis is a change of climate desirable: what are the principles which should govern us in choosing the kind of change to be made, and the best localities in North America to send patients of this class?" The prizes are open for competition by Medical editors only.

On Dec. 14th, there were 302 cases of small-pox under treatment in St. Petersburg, and twelve new cases and 3 deaths were reported. From the commencement of the outbreak on April 13th, 1872, to Dec. 20th, there were 4,441 cases (males, 2,819, females, 1,622); recoveries, 2,632 (1,713 males, and 919 females); and deaths 1,506 (927 males and 579 females).

The Royal Dublin Society will meet on Monday evening next at 8 o'clock, when the following communications are set down for reading:—

Dr. David Moore, Director of the Botanic Garden, "On the Successful Establishment of Loranthus Europæus on Oaks at the Botanic Garden, with Observations on the Cultivation of other Parasitical Plants therein."

Professor Tanner, M.R.A.C., "On the Comparative Trials of Fertilisers."

No person—saving, indeed, the fickle and ungrateful nation for whom he did so much, and from whom he suffered so bad a requital—has heard without deep interest the circumstances of the Emperor's death; but it is to our profession that the announcement brings a personal as well as a national importance. It is hardly open to us to doubt that so skilful an operator as Sir Henry Thompson, fortified by the advice of consultants so reverend as Sir William Gull, Baron Corvisart, and Dr. Conneau, treated the august patient with the soundest judgment and the utmost adroitness. Our speculations as to the relative propriety of lithotomy or lithotrity in such a case are worth little as compared with the verdict of those who could form their opinion from close observation. The result of the operative procedure, though in all probability quite unavoidable, is worthy of thought, for it cannot fail to leave upon the public mind a feeling not only that there was a miscarriage of surgical skill, but that the actual cause of death is insufficiently accounted for. We are, of course, aware that sudden syncope is possible, but it is an extremely rare occurrence for a patient with a good pulse of 84, to sink and die within twenty-five minutes, and we fail to find anything either in the speculations of the Profession or the records of the *post-mortem* examination which satisfactorily explains the fact.

Foreign Medical Literature.

ANEURISM OF THE ARCH OF THE AORTA.

By P. Coyne (Interne des Hôpitaux de Paris).

C. Therese, æt. 59, was admitted to the wards of M. Vulpian (Salle St. Claire, No. 27), at the hospital of "La Pitié," on the 19th July, 1871.

This patient menstruated when 13 years of age, was regular till 45 years old, when the menopause occurred. Her health has always been good, indeed, she has never been ill except from an attack of diarrhœa during the siege.

The symptoms for which she entered the hospital are not marked; she complains of feeling, during the last month, pains in the lumbar dorsal region, and in the head. But these pains are vague, and without special character. The voice has been hoarse for the last ten days, and the patient has had a cough for some time. At the apex of the heart a slight murmur is heard, with the first sound. At the base the second sound is indistinct. The examination of the lungs shows nothing special; percussion and pressure are, however, painful throughout the middle of the back of the left lung. The complexion shows a waxy cachexia, and the mucous membranes are anæmic. The uterus is normal.

20th July till 1st August.—Same indefinite symptoms continue. The patient still coughs and complains of pain in the back. The chest was examined but no confirmation could be found of the idea that aortic aneurism was present.

4th August.—At the evening visit the patient complained of a pain in the left side, originating from the middle of the vertebral column, and radiating over the whole side, especially at the back. Marked dulness at the lower part of the same side of the thorax. Higher up extending to the apex, almost tympanitic sonority exists both in front and at the side, with a maximum at the supra spinous fossa. No fluctuation can be felt. On account of the patient being hoarse, the vocal phenomena and the thoracic vibrations cannot be studied. Dyspnœa very great. Cough most troublesome. This condition commenced about an hour before our visit at which time the patient lay down without a cough or any efforts to cough, when the violent pain and the dyspnœa suddenly commenced, accompanied by great prostration and a tendency to syncope. The heart was carefully examined, but nothing abnormal discovered. Temperature in the rectum, 39 deg.

6th August.—At the morning visit the intensity of the pain and the dyspnœa had diminished. The extent of the sonority was less being limited to the supra scapular fossa behind, and to the infra clavicular region in front. A true "bruit skodique" is heard, whilst at the back and sides the dulness considerable. The intense blowing respiration which was heard the day before still continues.

The next day (7th) dulness extended over the whole left side. No spot remained sonorous. In the evening the same condition. In the course of the night the patient rose to go to the closet, where, a few moments after, she was found dead.

Post-mortem made 9th August.—Beyond an anæmic tint of the grey substance of the convolutions nothing abnormal is found in the cerebral organs, the cranial cavity, or in the abdominal viscera. Thoracic cavity, right pleura, nothing beyond a few adhesions on the convex surface. Left pleura contains about two litres of a liquid like serum. This liquid fills the cavity to the upper part, and pushes the left side of the diaphragm downwards. The lung is compressed against the vertebral column, and entirely covered by a reddish clot, which is not very dense, tears easily, is uniform in texture, and forms over all the lung a sort of thick shell, two or three centimetres in depth. A tumour formed by the dilatation of the third portion of the arch of the aorta is situated in front of the lung, and in the part which corresponds with the upper portion of the mediastinum. This tumour, about the size of a fist, is covered with rounded knobs, especially anteriorly, and they partly hide the left branch of the pulmonary artery at its entrance to the hilum of the left lung. The anterior surface of this tumour is covered by a pulmonary lobe which is tolerably thick, and united to it by old adhesions which are with difficulty broken down. When the anterior face of the tumour is isolated, the left pneumo-gastric nerve is seen to bury and lose itself in this front wall. The left recurrent nerve is at its origin similarly, but only partly, engulphed in the posterior wall. Behind and at the left, this tumour is adherent, as also the portion of the thoracic aorta immediatly following it to the middle part of the posterior border of the lung.

At the bottom of the highest part of the interlobular fissure, on separating the two lobes of the lungs having ragged edges and which is large enough to admit the little finger, is seen in the lung tissue. The pulmonary tissue around is indurated to the extent of two of three centimetres. This orifice leads into the cavity of the tumour. It is partly closed by old clots, which come from the inner wall of the aneurismal tumour. On opening the thoracic aorta by its posterior wall, it is seen that this tumour is formed by an irregular dilatation of the aorta taking place after the destruction of its internal coats. The inferior limit of the tumour corresponding to the point where the posterior wall of the aorta crosses the hilum of the left lung, has on its internal aspect an irregular, jagged border, floating in the cavity; this ridge-like swelling is formed by the two internal arterial coats. The principal development of the tumour is in front and outwards. On pushing the external coat from within several rounded diverticula are found and which correspond to the swellings on the outside. The principal is outwards, and has a depth of three centimetres; it is the one in which the ulceration previously mentioned originated. A calcareous scale, almost floating, is found partly imbedded in old clots at the bottom of the infundibulum. The left pneumo gastric which disappeared from the anterior surface of the tumour is found within the same anterior wall, covered by a thin layer of connective tissue. The superior limit of aneurismal dilatation is found immediately beneath the origin of the left subclavian artery. It is marked by a sort of little collar formed, like the inferior limit, by the two internal tunics, which, while well divided in front from the external tunic, are prolonged for some distance anteriorly, forming a sort of tongue. The internal surface is smoth, except where sclerous and calcified tongues still adhere by some points of their periphery. (The preparation was presented to the Anatomical Society.) This case is interesting from many points of view.

In the first place, it was difficult to recognise the lesion during life, and, though search was made in the right path, we consider its fruitlessness was due to the tumour being masked in a permanent manner, as the *post-mortem* examination showed, by a somewhat thick layer of pulmonary tissue. We call attention to the important fact that the perforation occurring as it did in a layer of pulmonary tissue which had previously undergone a modification, penetrated into the pleural cavity and brought on all the symptoms, first of pneumo-thorax, then of hydro-pneumothorax, and lastly, of abundant pleural effusion not producing death until three whole days after the first serious symptom.

Wurm on the Diphtheria Question.

Dr. Wurm makes the following remarks: "It is unfortunately incomprehensible to me, after an experience wanting neither in quality nor quantity, how physicians of celebrity can repudiate the sovereign means of timely, energetic, and persistent cauterizations in diphtheria, instead of giving this means the greatest possible popularity." As Dr. Wurm's thesis contains nothing otherwise essential, we will merely give his opinions on this point: He has until now, without exception, always effected a rapid convalescence by means of timely cauterizations with muriatic acid, which were repeated every one to three hours.

In the "murderous epidemic" all non-cauterized children died, while three which were well "touched" are well today. There follows the application, apparently as a result of it, a striking remission and euphoria, with moderation of the pulse, &c. Dr. Wurm complains that he has not time to give more than a glimpse of the clinical course of each case, as he has 300 bath-guests to attend from 5 a.m. to 10 p.m. He has only found time to affirm the above proposition with great earnestness, because three children who were "touched" are alive and well to-day.—*New York Medical Journal.*

Scarlet Fever in Lancashire.—At Midleton, near Manchester, scarlet fever is very prevalent, and the Improvement Commissioners have received a letter from the Local Government Board, urging upon them increased vigilance, as the disease also exists in a malignant form at Oldham, which is only a few miles from Midleton. Dr. Beard, Government officer, has been ordered to confer with the Midleton authorities on the measures to be adopted.

Literature.

TRANSACTIONS OF THE PATHOLOGICAL SOCIETY OF LONDON (a).

On several former occasions it has fallen to our lot to have to notice the proceedings of this valuable Society; and we confess we do so with much pleasure. We are not sure we could name any one direction in which medicine has made more important advances, within the last thirty years, than in the extended knowledge of morbid anatomy which has now been attained. We say extended; for it is not confined to this or that city or town, but to every place where medicine is systematically pursued. We also use the expression "morbid anatomy" with a distinct idea; for a great error is certainly made if it be confounded with pathology; and yet this is very apt to occur, and the very name "Pathological Society" has a strong tendency to increase this mistake. In our knowledge of morbid anatomy we have made immense strides of late years; whilst in pathology we are, in a great measure, stationary. We doubt if we have advanced a single step as to the causes of cancer, or other malignant disease; and all the labour bestowed on the microscope leaves us, on this point, precisely where we were half a century ago. Yet no one would think so from reading the volume before us, or others like it. For we find everywhere through them a large number of new terms, which, at first sight, would seem to be additional knowledge; but in reality are not so. There will be occasion to notice some examples of this as we proceed. It is far from our wish to discredit honest labour in any way. But labour may, and often does, take a wrong direction, and the sooner this is learned the better. The substitution of a new name for an old and well ascertained morbid state, seems to us but labour thrown away. We could pursue this subject much further, but it is not necessary to do so. For while we thus would criticise, we cannot overlook the great amount of valuable matter which a volume like the one before us contains; and without farther preface, we shall now—as on several former occasions—proceed to notice some of the more striking cases it contains. The first division of the volume is on "Diseases of the Nervous System," and the very first case, by Dr. Dickinson, is one of much interest. It is entitled "Sudden Death from the Bursting of an Intracranial Aneurism." It occurred in a female of 72, who, while eating her dinner, was observed to let her head fall forward, and she expired without a groan. She did not fall off her chair; nor had she been known to complain. On *post-mortem* examination, an aneurism, the size of a large pea, had burst. It had formed on the left middle cerebral artery, which, with the other vessels, now were all atheromatous. Effused blood lay on the base of the brain.

No. 2, by H. Amott, is a case of a boy of three years, who had excision of the elbow performed for strumous disease. From this he recovered; but in the course of some months was attacked with disease of the testis; and still later again with convulsions, which, after some interval, recurred, and ended in death. A scrofulous tumour, as large as a hen's egg, was found in the right middle lobe of the brain, with two or three of much smaller size in same side.

No. 3, by Dr. Peacock, is entitled "Case of Obstruction by Coagulum of the Cerebral Vessels, and Paralysis." We notice this case because, from reading such a heading, one would suppose the brain was alone involved; whereas pneumonia in a very active form also existed; and, what is of more consequence, in all probability gave rise to the brain affection. We have met such cases ourselves, and known them to occur to others. Yet the author does not allude to such a connection at all. We repeat, however, that the acute disease of the lung was most probably the starting-point of the fatal attack. It may be added that both the heart and liver were much enlarged.

No. 8, by Dr. Crisp, is entitled "Inflammatory Softening of the Cerebellum." We notice this case because the author has appended to it twenty other cases where the cerebellum was diseased; but in which the symptoms during life did not accord with the usually received opinions as to the functions of this portion of the nervous system. In this point of view the communication seems to us a very important one, and well worthy of perusal. But we also notice it because the author overlooks a most important morbid state, and which, we believe, had a great deal to say to the symptoms during life. The patient was a lady of 45, who, one year before her death, began to suffer from headaches, gradually increasing in severity, and which prevented her moving about with any quickness. In one of these attacks she died. Besides some softening of the under surface of the cerebellum, "many ounces of serum escaped, and all the space at the base of the brain, as well as the ventricles, were full of serum." We quote the words themselves, and must add it is not easy to understand how the author overlooked such a state. For, leaving out the state of the cerebellum entirely, such an effusion was sufficient to account for the symptoms. Yet not a word is said about such a connection. But we cannot pursue the subject farther here.

Diseases of the Organs of Respiration.

No. 1, by Dr. Robinson, is entitled "Case of Tonsillitis resulting in Sudden Death." This is the case of a soldier, æt. 21, who got common sore throat, as it was supposed, and treated as such. As he had not slept he was given a half-drachm of chloral, immediately after which he said he felt choking, and in a moment or two later expired. The trachæa was at once opened, but without any good result. This is a very important case, and the author avows he was totally unprepared for its sudden termination, and seems impressed with the idea that the chloral had something to say to the sudden death. For ourselves we would interpret the case differently. We think there was quite enough found after death to account for the event, for there was "great œdema of the glottis and infiltration of the tissues, one of the vocal cords being imbedded in it; the epiglottis, too, was greatly thickened and rigid." With such a state death is, if not constant, at least very common; and it is particularly worthy of note that, if the patient be at rest, there are not those signs of danger which exist so frequently with other acute diseases, and this exactly occurred in the present instance, for the author expressly states that "the general symptoms did not indicate any change for the worse since the morning, and that the issue was wholly unlooked for."

No. 5, by N. T. Norton, is an example of "Extensive Ulceration of the Trachæa." It extended from the true cords to the bifurcation, but was more extensive on the right than the left side, and in some places had healed. No mention is made of the state of the lungs, and we must presume they were healthy. Still, we should like to have had it so stated. We notice in this case, as, indeed, in many others through the volume, the tendency to connect all chronic diseases with syphilis. No doubt this poison is widespread, and its after effects varied and numerous. But its frequency cannot in our mind be compared with that of the strumous poison, if such it may be called. This is infinitely a more common source of disease, and yet it seems now-a-days to be greatly ignored, and the poison of syphilis put in its place. This error we observed in former volumes of these Transactions, and in some instances it was carried to an extent which no present knowledge justifies. In the case before us we believe the disease to have been essentially strumous. The syphilitic poison is, in our experience, very rarely localised in one part. This point is not one of mere curiosity. It entails questions of treatment of the very greatest consequence.

No. 6, by C. Kelly, M.D., is a rare case where a syphilitic ulcer of the right bronchus opened into the pulmonary artery, and so led to a fatal hæmorrhage. We do not recollect a case similar to this. But we have seen and known cases fatal, and from the same cause, in the throat; that is, the ulceration opened some branch of the carotid artery.

(a) "Transactions of the Pathological Society of London." Vol. XXIII.: Comprising the Report of the Proceedings for the Session, 1871-72. London: Printed for the Society, by J. E. Adlard, Bartholomew Close. 1872. Pp., 323.

No. 7 and 8, both by E. H. Greenhow, M.D., are examples of cirrhosis of the lungs, the disease described several years ago by Sir Dominick Corrigan; but no allusion whatever is made to his valuable paper, and what advantage arises from changing the name—now familiar to all in Dublin—we cannot tell. Not that the author uses another name, but that he speaks of "condensation and contraction of lung, dilatation of bronchial tubes," as if he were describing a state of disease not previously known. We think this is an advance backwards, and a hindrance to progress. If the same things be gone over and over again, with no change except using different words to describe them, how can progress be made?

Diseases of the Organs of Circulation.

Though there are many cases of interest in this section they do not call for more than a passing notice. The first two, by Drs. Goodfellow and Murchison, are examples of aneurism of the heart itself. The diagnosis of this state is, we believe, amongst the most difficult of any of the affections of this organ; and an approach to a certainty is the very utmost that can at any time be reached, and even that must be very exceptional. The ages of these two patients were forty-eight and sixty-three. The former was a man and the latter a woman, and in each the disease began with palpitations. A systolic murmur was present in each case.

No. 8, by R. King, M.B., is entitled, "Aneurism of the Aorta, associated with fracture of the first rib, and embolism of left middle cerebral artery." In this instance a heavy fall on the right shoulder seems to have led directly to the formation of an aneurism of the aorta. We presume the aorta must have been diseased when the injury was received; else it would be difficult to explain what occurred. And this view is borne out by the fact that considerable disease existed close to and in the left corpus striatum. This case is one of much interest.

No. 11, also by R. King, M.B., is "a case of congenital malformation of the heart associated with caries of the right mastoid bone, and abscess of the right cerebral hemisphere." The boy was aged four years, and the ventricles of the heart were found to have an opening between them. There was no cyanosis; and it was the symptoms caused by the abscess which were first noticed. The right side of the heart was nearly as thick in its walls as those of the left.

No. 12, by Dr. Crisp, is entitled, "Abcesses in the left wall of the heart in pyæmia." In connexion with this case the author has given a *résumé* of forty-two cases of a somewhat similar kind; that is, where pyæmia existed, and in nine of the cases, abscesses in the walls of the heart. It would seem as if males were more subject to this state than females; for the proportion is twenty-nine of the former to twelve of the latter.

No. 13, by C. Kelly, M.D., is "a case of fatal chorea, associated with valvular diseases of the heart." Besides recent deposits of lymph on the valves, there was also hepatisation of the lobe of the right lung; and in the brain each corpus striatum was diseased, as also the vessels about these parts. Before death the temperature rose to 106 deg. We have much yet to learn on this disease.

No. 14, by J. S. Townsend, is a rare example of "aneurrism of the left ventricle of the heart, in a state of ossification." It is strange this state seems never to have interfered with the functions of the organ; which weighed 15½ ounces. The aneurism existed at the apex of the ventricle, and was so much ossified as to require a saw to divide it. There were no adhesions.

Diseases of the Organs of Digestion.

No. 1, by J. F. Goodhart, M.B., is entitled "Casts from the intestine." They occurred in a female, æt. 43; and would seem to have had their origin in a previous attack of fever. Examination by the microscope showed the bodies were more of a solid nature, than that of casts. To us they seem to have been due to that disease—so little recognised—chronic enteritis. The patient suffered from great constipation, and general abdominal pain.

No. 2, by S. M. Bradley, is entitled, "Adhesion of the velum pendulum palati to the posterior wall of the pharynx; loss of the epiglottis syphilis." We notice this case because it seems to us to have been as likely caused by strumous diseases as by syphilis. All the results found here will, we know, be caused by the former disease. No history of syphilis is given, and on the other hand the man died of phthisis.

No. 3, by J. H. Galton, M.D., is an instance of "perforation of the bowel in typhoid fever." The patient was a boy of 12, and the case in itself a slight one; the temperature never exceeding 101½ deg., there were no rose spots.

No. 4, by J. C. Thorowgood, M.D., for Dr. P. James, "is a case of salivary calculus removed from the orifice of the parotid duct." We notice this case because the presence of the calculus was overlooked for some years. It gave rise to much suffering and loss of flesh; and after its removal the patient began at once to recover flesh and health. The calculus weighed 93 grains, and was composed chiefly of phosphate of lime.

No. 5, by J. B. Peacock, M.D., is a very important case entitled: "Fatal constipation from excessive dilatation of the colon." A man of 28 was subject from birth to confined bowels, which were treated, even while still a child, by purgatives. In 1860 he had a severe attack of obstruction, which, though relieved, left after it still more obstinate constipation. He was never free of swelled abdomen, often amounting to tympany; and died after an attack which reached over six weeks, and on *post-mortem* examination not only was the colon found of great size, but it was also ulcerated in patches. We should like in this important case, to have known what light the microscope would have thrown on the state of the muscular fibres. The peritoneum was quite free.

No. 6, by C. T. Williams, M.D., is a case of "Ulceration of the vermiform appendix giving rise to limited peritonitis." This case will well repay perusal; but it is too long for further notice here.

No. 7 and 8, by H. Amott and W. F. Clark, are each examples of "congenital hypertrophy of the tongue." These are rare cases; nor have we seen any such, except in the adult. In the cases before us an operation was performed on each, and in one successfully. It would seem as if the morbid growth which protruded beyond the mouth was entirely due to an hypertrophied state of the natural texture of the tongue.

(To be continued.)

Correspondence.

MEDICAL ETHICS AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having read with great interest the very sensible letter which appeared in your last week's number by "A Hard-working Practitioner," I desire, with your permission, to offer him my best thanks. To me his remarks appear unanswerable, and all honest, thinking members of the Profession will admit the force of his argument. I object quite as strongly as Mr. Charles Hawkins to see, as I did in *The Times* a few days since, a whole column advertisement of a Medical man, and I also object to advertisements being perpetually inserted in large numbers of the non-Medical press; both are to my mind derogatory to the dignity and honour of our calling. But I can see no possible objection to the occasional insertion of an ordinary book announcement in the columns of the lay press. Consulting-surgeons do not get the bulk of their patients from general practitioners, and as the

Medical journals are supposed not to be read by the public, they have no alternative left them but to let those who suffer disease and desire to be healed know through the medium of the general press what works have been written upon each individual subject. It is very well for those who are rich and can afford to wait for grey hairs before they get a practice to protest, but let such men be honest, and not stigmatise their less fortunate brethren, who are compelled by circumstances over which they have no control to strive by legitimate means to make that practice for which the state of their finances does not allow them to wait an indefinite period.

I am, Sir,
Yours, &c.,
AN AUTHOR.
London, Jan. 9th.

LONDON *VERSUS* COUNTRY PRACTITIONERS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Should you think the following case sufficiently interesting, perhaps you will find space for it in your independent columns. I think it will be evident that there has been either ignorance or neglect; at all events, it is but one out of thousands, for the idea is—"Run up to London, you will get the best advice there; these country doctors are not to be depended upon." I have heard the above remarks frequently, but truth and error are found on both sides; however, country practitioners are partly to blame for this, they are jealous and quarrel with each other, and prefer sending from fifteen to a hundred miles for a stranger, perhaps less talented than the man at his door—than calling him in—to grab away his patient!! A lady, a dark brunette, above the middle size, and of sedentary habits, has been ill for some time, and went to London for advice; has been at different times under the care of three of the most celebrated physicians, and became gradually worse instead of better. None of them would tell her her complaint, except that one told her that "her nervous system was very much shattered, and she required sea air and moderate exercise;" another, that "her bilious system was out of order;" and the third, that "she required tonics, country air, and patience, and she would get well in time." She returned to the country, placed herself under Medical care, and got no better. "I want to try you," she said, "if you can give me anything to relieve me, I am tired of taking medicine; but what can I do? I am afraid I am past cure." She was lying upon a sofa propped up with pillows; pulse 112 and easily compressed; skin dry and rather hot; headache; tongue very dirty, covered with a dry thick brown crust, from the tip to the root; its sides were natural; mouth clammy and taste very bitter; breath offensive; no appetite; pain of right hypochondrium and on pressure, pain over both kidneys and on pressure; urine very high coloured, offensive, with a quantity of dark brown sediment; constitutional constipation; one motion two days past, very hard, black, and offensive; languor and listlessness; no sound sleep for months past; dreams haunt her continually; occasional nocturnal sweats; she had a wearied look. "Have you done?" she said, "I have answered all those questions before, and no good came of it." Stomach very irritable and rejects everything, except tea. "That stuff"—pointing to some saline mixture she was taking for her stomach—"comes up as fast as it goes down. I will take no more of it, Doctor; I am afraid you are like the others, and will do me no good." "I will restore you to health if you will implicitly obey my orders." "Ah! Doctor, that is sweet music, I have heard it before, and paid for it pretty heavily; but, I said I would try you and I will, I will obey you to the very letter." There was much thirst.

℞ Ol. crot. zig. gutt., ij.;
Mucil. acac., ʒij.;
Aq. ad. ℥ij. M.

One dessertspoonful every fifteen minutes till it operates. She took four, rejecting each a few moments after swallowing; however, before the fifth could be given it operated in a copious discharge of highly offensive matter. Three evacuations followed in a few hours, containing some fæcal matter and a quantity of scyballæ, four of them as large as good sized marbles. Had a tablespoonful of sherry after the first evacuation, which remained.

28th July, 6 p.m.—It is eight hours since I first saw her; she says she feels much relieved, but is very much exhausted. Dry toast and tea and a quarter of a grain of the muriate of morphine.

29th, 10 a.m.—Has had a "most heavenly sleep;" both headache and pain of side are gone; the other pains are easier; skin moist; pulse 100; stomach easy; no nausea; less thirst; one liquid stool this morning; urine as yesterday.

℞ Quass. gent. rad. zingit. jam. cont., ʒiij.;
Utrinsque aq. bullient, ℈j. Infuse.

℞ Nitrat. potass. sp. æth. nit., āā ʒij.;
Sp. ammon. arom., ʒj.;
Infus. quass. comp., ℥viij. M.

One tablespoonful to be taken every six hours. Dry toast and tea mornings and evenings. Rice and the gravy of Australian beef to be kept warm, and taken in small quantities when inclined.

℞ Morph. mur., gr. ij.;
Sacch. alb., ʒij.;
Aq., ℥ij. M.

One tablespoonful to be taken every six hours.

30th, 10 a.m.—Ah! Doctor, I feel so happy, but I am going all the same, weaker and weaker. We can only hope, I said, and mine were very favourable. Pulse 76; tongue cleaning; used the acid of lemon with sugar and a tooth brush; urine not so red; no pain whatever; stomach very comfortable; continue mixture of quassiæ every three hours.

31st, 10 a.m.—Improving; some appetite; urine very much clearer; less sediment and less offensive; no thirst. Has not menstruated for five months until to day. This obstruction I forgot to mention—*Habeat statim.*

Pulv. colocyn. comp., gr. x.

Aug. 1st.—Still improving; sleeps well; pulse steady, at 76. One tablespoonful of sherry after each meal; continue medicine; bowels moved.

3rd.—Very much improved; can walk across the room; tongue clean; mouth comfortable; urine clear; no sediment; enjoys a little beefsteak with rice in the gravy; continue medicine.

6th.—Still improving; omit the quassiæ mixture.

℞ Ferri et quiniæ citrat., ʒij.;
Infus. quass. comp., ℥viij.
M. Coch. amp., ij. *Quartis horis.*

10th.—Garden exercise.

15th.—Has left off medicine; health quite restored.

I am, Sir,
Your obedient servant,
ALEXANDER LANE, M.D., R.N.
Ludlow, Salop.

Medical News.

Pathological Society of London.—The annual meeting of this Society was held on the 7th inst., when the report for the past year was read by Mr. Hulke, one of the hon. secretaries. The balance-sheet showed that a sum of over £90 was due to the Society after the payment of the current expenses. The following new bye-law was then passed: "That the trustees shall be *ex officio* members of the Council." The officers for the ensuing year were then elected—viz.:—President: Sir William Jenner, Bart., M.D., D.C.L. Vice-Presidents: Drs. Dickinson, Quain, and Burdon-Sanderson; Messrs. Cooper Forster, Hilton, Hulke, Hutchinson, and Wood. Treasurer: Dr. Murchison. Honorary Secretaries: Dr. Cayley and Mr. Arnott. Council: Drs. Broadbent, Cholmeley, Selby Church, Langdon Down, Duffin, H. Green, Hughlings Jackson, C. R. Nicoll, Pavy, J. Frank Payne, R. Douglas Powell, and Frederick Robinson; Messrs. Wm. Morrant Baker, Wm. Fairlie Clark, H. J. H. Lawrence, Francis Mason, and Arthur B. R. Myers; Dr. Henry Cooper Rose, Mr. Henry Smith, and Dr. John Way.

Quacks and Victims.—Henry Jackson, the quack doctor who has just been convicted of obtaining money upon false pretences, no doubt richly deserves the sentence of twelve months' imprisonment with hard labour which has been pronounced upon him. At the same time it is difficult to resist the conviction that Mr. Richardson, the prosecutor, was a pigeon whom it was almost impossible for a man with the slightest tinge of roguery in him, to resist the temptation to pluck. A man who, having read Dr. Rook's book, in which that eminent personage says, "Presuming on the liberty of British subjects, I have ventured to express my opinion, that all Medical systems hitherto promulgated in this country are entirely false," becomes convinced that he is suffering from "debility," pays £1 1s. for a "bottle of electric shock," £25 for a box of the "great Indian remedy," £20 16s. 6d. for the "Indian medicine chest," 30s. for a box of "gums and balsams" which were "a mass of electricity," "supposed to be the same spikenard which anointed the feet of our Lord;" £51 for a box of the "Bread of Life," that he understood to be "manna" which had been "left by the Children of Israel" upon trees which had been transplanted to British India,—such a man as this, we say, has scarcely a right to complain if a rogue does him out of his money. Mr. Richardson, we may add, has been engaged in the management of a farm of 500 acres. Clearly, agriculture requires looking after.—*Echo.*

University of London.—By the resignation of Dr. Hirst, the office of Assistant-Registrar has become vacant. His successor will be charged with the duties of the librarian. The salary is to be £500 a year.

Fever at Moseley.—Dr. Ballard has been sent as Government Inspector, to examine the causes of the epidemic of typhoid fever which has been recently prevalent at Moseley.

Royal Navy.—Notice is given of a competitive examination of candidates for admission into the Medical Service of the Royal Navy, which will take place at the University of London on Monday, the 17th of February.

◆

Scraps from the Editor's Table.

THE YOUNG DOCTOR.

In Dr. Oliver Wendell Holmes' last story, "The Poet at the Breakfast Table," in the *Atlantic Monthly*, occurs the following :—

"The young doctor has a very small office and a very large sign, with a transparency at night big enough for an oystershop. These young doctors are particularly strong, as I understand, on what they call 'diagnosis'—an excellent branch of the healing art, full of satisfaction to the curious practitioner, who likes to gives the right Latin name to one's complaint; not quite so satisfactory to the patient, as it is not so very much pleasanter to be bitten by a dog with a collar round his neck, telling you that he is called *Snap* or *Teaser*, than by a dog without a collar. Sometimes, in fact, one would a little rather not know the exact name of his complaint, as if he does he is pretty sure to look it out in the Medical dictionary, and then if he reads—*This terrible disease is attended with vast suffering, and is inevitably mortal*, or any such statement, it is apt to affect him unpleasantly.

"I confess to a little shakiness when I knocked at Dr. Benjamin's office door. 'Come in!' exclaimed Dr. B. F., in tones that sounded ominous and sepulchral. And I went in.

"I don't believe the chambers of the inquisition ever presented a more alarming array of implements for extracting a confession than our young doctor's office did of instruments, to make Nature tell what was the matter with a poor body.

"There were ophthalmoscopes and rhinoscopes, and otoscopes and laryngoscopes and stethoscopes; and thermometers and spirometers and dynanometers and sphygmometers and pleximeters; and probes and probangs, and all sorts of frightful inquisitive exploring contrivances; and scales to weigh you in, and tests, and balances and pumps, and electro-magnets and magneto-electric machines; in short, apparatus for doing everything but turn you inside out.

"Dr. Benjamin sat me down before his one window and began looking at me with such a superhuman air of sagacity, that I felt like one of those open-breasted clocks which make no secret of their inside arrangements, and almost thought he could see through me, as one sees through a shrimp or jelly-fish.

"First, he looked at the place inculpated, which had a sort of greenish-brown colour, with his naked eyes, with much corrugation of forehead and fearful concentration of attention, then through a pocket-glass which he carried. Then he drew back a space, for a perspective view. Then he made me put out my tongue, and laid a slip of blue paper on it, which turned red and scared me a little. Next he took my wrist; but instead of counting my pulse in the old-fashioned way, he fastened a machine to it that marked all the beats on a sheet of paper—for all the world like a scale of the heights of mountains, say from Mount Tom up to Chimborazo, and then down again, and so on.

"In the mean time he asked me all sorts of questions about myself and my relatives, whether we had been subject to this and that malady, until I felt as if we must some of us have had more or less of them, and could not feel quite sure whether elephantiasis and beriberi and progressive locomotor ataxy did not run in the family."

◆

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this request.

All communications intended for insertion must bear the name and address of the writer; not necessarily for publication, but as a voucher of good faith.

Subscriptions in the United States.—A correspondent has drawn our attention to the fact, that some of the houses in the United States are charging the enormous figure of 15 dollars per annum (more than £3) for supplying this Journal to different parts of the States. We beg, therefore, to state that we shall be happy to supply the same regularly, post free, per annum, if paid in advance, for considerably less than half this amount, viz., six and-a-half dollars (about £1 6s. 0d.), either direct from our offices in this country, or through our recognised agents in the United States.

ANCIENT SURGICAL INSTRUMENTS AT THE INTERNATIONAL EXHIBITION, 1873.

It has been suggested to Her Majesty's Commissioners that, in the class of "Surgical Instruments and Appliances" of this year's Exhibition at South Kensington, there might be included representative collections of ancient instruments, or of those used by celebrated surgeons in different ages. For example, steps have already been taken to obtain, through A. Castellani, of Rome, reproductions of the well-known surgical instruments discovered at Pompeii, and now exhibited in the museum at Naples. It is hoped that the implements used by the old English surgeons will also be well represented. Mr. Charles Hawkins has promised to send those used for lithotrity by Sir Benjamin Brodie. Mr. T. Wormald has offered those which belonged to Mr. Abernethy. Mr. Liston's will also be shown; and it is believed that there exist, in many museums and private collections, curious and ancient surgical instruments which would show the progress of the art of surgery, and form a most interesting and instructive series if collected together next April for public exhibition and professional study. The possessors of any such specimens can obtain all necessary particulars as to the cases &c, provided to exhibitors, on application to the secretary of the Royal Commission, Gore Lodge, S.W.

Mr. W. (Glasgow).—You will find it in another column.

Mr. Mather (Manchester).—Our exchange list is already so very large that we do not care to extend it.

Medical Wills.—Under this heading in our "News column," we accidentally killed a gentleman for whom we entertain the highest respect, and who, we are proud to say, is still alive and well. Fortunately, we had not time before going to press with our last number, or he might have had the pleasure and amusement of reading his own "obituary," as was the case with Lord Brougham, and others. We therefore apologise to Mr. Richard Partridge, F.R.S., of King's College, and rectify our error by stating that the death which took place was that of his brother, Mr. John Partridge.

Dr. McGregor Croft.—We shall be glad to insert a letter upon the subject.

Mr. John Pearce.—We think the addition of the Turkish bath to existing bathing establishments would be desirable.

The Naval Medical Service.—A competitive examination of candidates for admission into the Medical Service of the Royal Navy will be held at the University of London, on Monday, February 17th, and following days. Candidates must present themselves four days previously.

S. E. R.—These outbursts of virtuous indignation by our contemporary are excusable; we quite agree with you that they lose their weight by such frequent repetition, especially when the censer is the most frequent offender in the matter it affects to condemn.

VACANCIES.

University of London. Assistant Registrar and Librarian. Salary £500 per annum, subject to annual re-election. Applications, stating age and previous occupation, to be sent to the Registrar at the University offices.

Bolton Infirmary. Senior and Junior House Surgeons. Salary £120 and £100 respectively, increasing £10 yearly. Board and residence. Applications to the Secretary.

Nottingham. Medical Officer of Health for the Borough. Applications for particulars to be addressed to Mr. S. G. Johnson, Town Clerk.

Manchester Royal Infirmary Dispensary and Lunatic Asylum. Two Assistant-Physicians; two Assistant-Surgeons; one Obstetric Surgeon; Ophthalmic Surgeon, and Dental Surgeon. These appointments are all honorary. Applications must be sent in before the 18th inst.

District Lunatic Asylum, Ireland, Londonderry district. Resident Medical Superintendent. Applicants must be qualified in Medicine and Surgery. Applications to Dublin Castle. (See advt).

Sligo Union. Sligo Dispensary District. Qualified Apothecary. Salary £80 per annum. (See advt.)

Ryde Infirmary, Isle of Wight. Surgeon. Honorary.

Stockton-on-Tees Dispensary. Apothecary. Salary £120, non-resident. Applications to the Honorary Treasurer.

Brighton and Hove Lying-in Institution. House Surgeon. Salary £100 per annum, with residence. Applications to the Chairman of Committee.

Islington Dispensary. Medical Officer. Salary £160 per annum, with residence. Applications to the Honorary Secretary.

Leicester Provident Dispensary. Medical Officer.

St. Mary's Hospital for Women, Manchester. Resident Medical Officer. Salary £60 per annum, with board. Application to the Secretary.

◆

APPOINTMENTS.

Barham, Mr. H. F., House-Physician to Addenbrooke's Hospital, Cambridge.

Beckingsale, D. L., House-Surgeon to the Huntingdon County Hospital.

Carter, W., M.B., Medical Officer of Health for West Derby, Lancashire.

Davies, J., M.R.C.S., Medical Officer for District 2 of the Bath Union.

Hatton, J., L.R.C.P. Ed., M.R.C.S.E., Medical Officer of Health for the Coleford District of the Monmouth Rural Sanitary District.

Hodges, W., L.R.C.P., Medical Officer of Health for Horfield, Gloucester.

Lane, J., M.R.C.S.E., Medical Officer of Health for the Skenfreth District of the Monmouth Rural Sanitary District.

Lewis, Mr. G., Public Analyst for the Borough of Monmouth.

Malins, E., M.D., M.R.C.S.E., an Hon. Medical Officer to the Birmingham Lying-in Charity.

Mayou, G., M.D., M.R.C.S.E., Medical Officer of Health for the Monmouth Urban Sanitary District and the Trelleck District of the Monmouth Rural Sanitary District.

Norman, A. B., L.R.C.P.Ed., M.R.C.S.E., Medical Officer for the Ilkeston District of the Basford Union.

Norman, G. A., M.B., L.R.C.P.Ed., Medical Officer of Health for the Rockfield District of the Monmouth Rural Sanitary District.

Ryding, G., M.D., M.R.C.S.E., Medical Officer of Health for the Neath Urban Sanitary District.

Sellers, W., M.R.C.S.E., Medical Officer of Health for the Radcliffe Urban Sanitary District, Lancashire.

Shepard, H. C., M.R.C.S.E., Medical Officer of Health for the Ragland District of the Monmouth Rural Sanitary District.

Stevenson, T., M.D., Public Analyst for Bedfordshire.

Tripe, J. W., M.D., Public Analyst for Hackney.

Warner, F., M.B., M.R.C.S.E., House-Surgeon to the Royal Surrey County Hospital, Guildford.

Whamond, W., M.D., Medical Officer and Public Vaccinator for the Jarrow District of the South Shields Union.

Woollett, J. M., M.R.C.S.E., Medical Officer of Health for the Monmouth District of the Monmouth Rural Sanitary District.

MEETINGS OF THE LONDON SOCIETIES.

Thursday, January 16.

Royal Institution, 3 p.m.—Dr. Debus, "On Oxidation."

Hunterian Society, 7½ p.m.—Council. 8 p.m.—Mr. Hutchinson, "On the Laws of the Hereditary Transmission of Gout."

Friday, January 17.

Royal Institution, 8 p.m.—Mr. W. M. Spottiswoode, "On the Old and New Laboratories at the Royal Institution."

Saturday, January 18.

Royal Institution, 3 p.m.—Dr. Edward A. Freeman, "On Comparative Politics."

Monday, January 20.

Medical Society, 8 p.m.—The Second Lettsomian Lecture "On Prostatic Discharges," by Mr. Henry Lee.

Tuesday, January 21.

Royal Institution of Great Britain, 3 p.m.—Professor Rutherford "On the Forces and Motions of the Body."

Pathological Society, 8 p.m.—Ordinary Meeting.

◆

Marriages.

Dyer—Gwynne.—On the 9th January, at St. Mary's, Tenby, Samuel Webb Dyer, LL.B., of Cromhall, Gloucester, to Katherine Frances Mary, only daughter of Daniel W. Gwynne, Esq., M.D., of Tenby, S. Wales.

Ellis—Fincham.—On the 8th January, at St. Peter's, Westminster, Captain C. H. Fairfax Ellis, R.A., to Alice Anna, eldest daughter of George T. Fincham, M.D., 16 Belgrave Road, S.W.

Fletcher—Stogdon.—On the 9th January, at Barton Stacey, Hants, Dr. George Fletcher, of Earl Soham, Suffolk, son of Dr. Fletcher, formerly of Bromsgrove, to Annie, eldest daughter of the Rev. A. H. Stogdon, M.A., vicar of Barton Starcey.

Fowler—Martin.—At St. Werburg's, Derby, Charles Busterd Fowler, son of the late Richard Fowler, Esq., M.D., Cork, to Mary Elizabeth, daughter of W. S. Martin, Esq., Burton-on-Trent.

Madden—Rose.—On the 7th January, at the Roman Catholic Church, Belmullet, Henry J. Madden, Esq., M.D.Q.U.I., Ballycastle House, County Mayo, to Lizzie, second daughter of Arthur Rose, Esq., Sea View, Belmullet.

Stephenson—Walsh.—On the 9th January, at Stoke Bishop, near Bristol, T. Appleby Stephenson, M.D. (Edin.), Mottingham, to Mary Louise, third daughter of D. B. Walsh, Esq., Clifton, Bristol.

◆

Deaths.

Hamerton.—On the 3rd January, at Elland, Yorkshire, Ernest Hamerton, M.R.C.S.E.

Hutchinson.—On the 2nd January, at Bishop-Auckland, Jane, wife of V. Hutchinson, M.D.

Kennedy.—On the 8th January, at 1 Upper Merion Street, Dublin, Edith, Emily, the youngest daughters of Evory Kennedy, M.D., aged 16 years.

Lewis.—On the 4th January, at Berkeley Street, Prince's Park, Liverpool, David Lewis, M.R.C.S.E., of Newport, Monmouthshire.

Smedley.—On the 28th December, Nathan Smedley, L.R.C.P.Ed., of Bolton, Lancashire, aged 23.

Smith.—On the 23rd December, E. Smith, M.B., L.R.C.S.I., of Bayview Terrace, Londonderry, Resident Medical Superintendent of the Londonderry District Lunatic Asylum, aged 34.

NOTICE OF EXAMINATION OF CANDIDATES FOR THE NAVAL MEDICAL SERVICE.

NOTICE is HEREBY GIVEN that a COMPETITIVE EXAMINATION of Candidates for admission into the MEDICAL SERVICE of the ROYAL NAVY, will take place at the University of London, Burlington Gardens, on MONDAY, 17th Feb., 1873, and following days, at 10 o'clock.

Candidates must present themselves at this Department on Thursday, 13th February, 1873, bringing with them the various Certificates of Qualifications specified in the Regulations of the 24th June, 1871, when, should they be found in all respects eligible, they will be permitted to appear for Examination.

A. ARMSTRONG, Director-General.

Naval Medical Department, Admiralty, Somerset House, W.C.,
January 6th, 1873.

THE HOSPITAL FOR WOMEN, SOHO SQUARE.

A Course of LECTURES will be delivered at the Hospital during the months of January, February, and March, 1873.

Dr. ALFRED MEADOWS will lecture on "Fibroid Tumours of the Uterus," on Thursdays, January 16th and 23rd.

Dr. HEYWOOD SMITH, on "Cancer Uteri" on Thursdays, January 30th and February 6th.

Mr. CHRISTOPHER HEATH, on "Diseases of the Female Urinary Organs" on Thursdays, February 13th and 20th.

Dr. ARTHUR W. EDIS, on "Miscarriages" on Thursdays, February 27th and March 6th.

Dr. SQUAREY, on "Ovaritis and Ovarian Dysmenorrhœa" on Thursdays, March 13th and 28th.

Each Lecture will commence at 8.30 p.m. Gentlemen proposing to attend can obtain Cards of Admission on application to HENRY B. INGRAM, Secretary.

SURGICAL SOCIETY OF IRELAND.—The next MEETING of the SOCIETY with take place on FRIDAY evening next, the 17th inst.

The Chair will be taken at half-past Eight o'clock precisely.

B. WILLS RICHARDSON, F.R.C.S.I., } Hon. Secs.
JOLIFFE TUFNELL, F.R.C.S.I., }

Royal College of Surgeons, Dublin,
15th Jan., 1873.

CONWAY GRAMMAR SCHOOL.—During the last two years, Boys from this School have passed the *Preliminary Examinations* of "*Physicians and Surgeons*," *Glasgow*; "*Apothecaries' Hall*," *London*; and the "*Incorporated Law Society of Great Britain*." Inclusive terms for boarders £8 per quarter. (*Classics, Mathematics, Modern Languages, Music, and Drawing*). Sea and mountain air.

Address, Mr. Fawcett, Conway, North Wales.

DISTRICT LUNATIC ASYLUMS, IRELAND.

THE OFFICE OF RESIDENT MEDICAL SUPERINTENDENT of the DISTRICT LUNATIC ASYLUM, LONDONDERRY, being now vacant, Candidates for that office are requested to forward their testimonials, with a statement of their peculiar qualifications for the appointment, to the Under Secretary, Dublin Castle, on or before the 15th day of JANUARY next, in order that the same may be submitted to His Excellency the Lord Lieutenant.

Applicants must be duly qualified to practice both in Medicine and Surgery, and registered as such under the Medical Act of 1858.

Candidates are requested to specify their age.

The Candidate who may be selected for the office in question, will have to enter upon his duties forthwith.

Dublin Castle, 28th December, 1872.

THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.

PATRON:—H.R.H THE PRINCE OF WALES.

This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develope the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £35 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote.

Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c., can be had at the office,

40 MOLESWORTH STREET, DUBLIN,

W. O'NEILL, Secretary.

THE Friends of a YOUNG GENTLEMAN, who labours under occasional MENTAL HALLUCINATIONS, are anxious to place him in the family of a Medical Gentleman, who will undertake the treatment of his case.

For particulars, apply to DR. HADDEN, of Skibbereen.

TO PHYSICIANS.—The friends of a Lady whose mind is occasionally affected, desire to place her in a PHYSICIAN'S FAMILY, where she would be treated with care and kindness, and have a happy home. Please state Terms in reply. References given and required.—C. E., Donoughmore, Co. Tyrone.

THE EARL STREET MEDICAL AND DRUG HALL.

J. LEONARD and CO. beg to inform the Medical Profession and Public in general that they have become Proprietors of the above old established Concern, recently in the possession of the late Mr. J. King.

In addition to the usual supply of Drugs and Family Requisites for which this Establishment has been long celebrated, J. L. and Co. have the pleasure to announce that, being Licentiate Apothecaries, they have opened a Compounding Department for the dispensing of Prescriptions under their own immediate supervision, with Medicines of the purest quality, and they trust that this arrangement will be found a great convenience not only to the numerous customers of the Establishment, but also to the inhabitants of the north side of the City.

May 8, 1872. 19 NORTH EARL STREET, DUBLIN

The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements, from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

The scale of charges is as follows:—

Seven lines and under	£0	4	0
Per line afterwards	0	0	6
One quarter page	1	5	0
Half-page	2	10	0
One do.	5	0	0

When advertisements are given for a series of insertions, a very considerable reduction from the above scale is made.

☛ Advertisements for Insertion in this Journal must be at the OFFICE, on SATURDAY, by Two o'Clock.

Established 1848.

PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE,

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY LL.D., M.R.C.S., F.L.S.,

&c. (KING'S COLL.), and Author of VIA MEDICA,

Has always upon his books a large number of desirable Investments and available Appointments for negociation.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application. Office hours, from 11 till 4; Saturdays excepted.

COMPETENT ASSISTANTS provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

PRACTICES AND PARTNERSHIPS NOW OPEN for Negociation (in addition to those advertised in Dr. Langley's List (which is sent post free on application).

Y 568. First Class PRACTICE near LONDON, established nearly forty years; average receipts upwards of £700, but could promptly be doubled by a suitable gentleman, as buildings of a good class are being erected all around. The vendor being an invalid, has not been able to push the practice actively, but can transfer the connexion to a gentleman of good qualifications. One horse and brougham sufficient to conduct the practice. There are two appointments causing little trouble, but affording a useful introduction. Midwifery fees, £2 2s. and upwards; large modern house, with conservatory, garden, &c., and every convenience. There is direct railway communication with London, and frequent trains.

Y 613. In a Pleasant Town in a SOUTHERN COUNTY, a well-established PRACTICE capable of considerable increase, realizing about £500 a-year. Appointments £150. Very little opposition. Expenses small.

Y 612. LONDON. OPEN SURGERY without Retail. A well-established connexion in a populous district, capable of great extension. The incumbent is compelled to retire in consequence of ill health. Patients, good middle class. Midwifery fees, £1 1s. and upwards. No horse or carriage required. Convenient house, &c. Rent, £40. The receipts have been lately at the rate of about £200 a year, but the incumbent has not been able to give the business proper attention, and it is believed that £500 a year could be realized promptly by an active gentleman. The surgery is well fitted and stocked, and the situation unquestionably good.

Y 611. SOUTHERN COUNTIES. PARTNERSHIP. A Surgeon, long-established, with a Practice of about £1,600 a year in a small but wealthy town, desires to secure the Co-operation of an active junior, to whom one-fourth of the income, half the appointments and midwifery would be allotted. The public appointments would probably amount to about £250 a year. There is no opposition, and the practice includes the best families in the locality. Premium, £800, part of which might be left on security.

Y 609. PRESCRIBING PRACTICE in a Cathedral Town; old and transferable to a suitable gentleman. Receipts, from £1,000 to £1,200 a year, earned with little labour. Midwifery cases have been taken occasionally at fees from £2 2s. to £3 3s. One horse and carriage. Convenient house in a good situation, with stabling, &c. Rent, £52. The successor should be acquainted with Eclectic practice.

Dr. LANGLEY'S QUARTERLY LIST of Selected Practices and Partnerships, for JANUARY, is now ready, post free on Application.

The Medical Press & Circular.

INJURIES OF THE SPINE, THE RESULT OF RAILWAY CONCUSSIONS.

By J. Morgan, M.D., F.R.C.S.I.,

Surgeon to Mercer's Hospital, and Lecturer on Surgical and Descriptive Anatomy R.C.S.I., &c.

(*Continued from page* 40.)

Cases have already been recorded where "railway spine" has ensued from collisions which seemed comparatively trivial in their nature, and where the recipient at the time thought that nothing had happened, but the *bouleversement* consequent on the accident, the progressive and insidious advance of serious symptoms, however, too often have proved the error of under-estimation of these injuries. This is remarkably illustrated by a case related by Mr. Erichsen.

"A surgeon, æt. 43, stout and active, was in a railway collision, by which he was thrown forward, but without any great violence. He received no blow on the back, head, or other part. He was much frightened, but did not lose consciousness. He did not suffer for the first three or four weeks, but was not able to attend to his business. In about a month he suffered from pain in the loins; he had lost weight and strength. Four-and-a-half months afterwards he was much in the same state, but was obliged to give up his practice, not owing to mental, but entirely to bodily infirmity. The spine generally was tender, and pain was increased by manipulation or percussion; he had numbness and formication in the right and sometimes left leg; walked in a straddling way; if told to stand on his toes immediately fell forward, and did not know exactly where to place his feet."

Seven months after the accident he was again examined, and his condition was found in no way improved—indeed, in some respects it had progressively become worse.

This case was settled out of court for £2,500—a judicious proceeding, it may be supposed, for the company, as the blighting of the hopes of success in life of a Medical man at his age should be valued at a higher ratio by any reasonable jury.

The following instance has come within my own observation, and illustrates some of the uncertainties of the results of railway concussions, showing that the intensity of apparent shock, or the evidences of direct injury to the surface at the time cannot be counted on as a presage of the after-course of the disease. As the sufferer was in this instance a surgeon, and a gentleman of undoubted intelligence and veracity, the record of his symptoms, many of them given by himself, is important. He was starting in his profession, full of life and energy, and was settling in one of our largest northern towns, but by the unfortunate collision was so severely injured that he had to relinquish his undertaking, and lead the life of an invalid for many months, from which condition even at the present moment he has not recovered; yet a jury awarded him the miserably insufficient sum of £650 in compensation for his annihilated prospects, his bodily sufferings, and the inevitable danger he had to go through, and even then with doubtful ultimate results. Counsel on the opposite side went so far as to characterise his statements as gross exaggerations. His own account, however, speaks for itself:—

"The first thing I recollect after the smash, which took place on the 13th May, 1871, was lying on the floor of the first-class carriage, covered with the cushions and dust. I had previously been sitting with my back to the engine, not actually in contact with the back of the carriage, but rather leaning forward in conversation with a fellow-passenger. I was the first to get up and help the others out; I went towards the smash along the side of the embankment to see if I could be of any use. The injured had been attended to before I got there, and I returned along the line to help my fellow passengers, whom I thought I recognised crossing an adjoining field. I attempted to join them, and with great difficulty got over a ditch, and through a quickset hedge. I then thought night came on quite suddenly, it got so dark; but my sight was totally gone, as I came against cattle several times without seeing them at all. The blindness lasted until I was roughly accosted by a man, into whose garden I had stumbled. He put me on the road; I groped my way along it like one drunk, until I heard a car, on which I got, and drove into town. . When I got off the car my sight was better, and I was in a most excited state, stopped people in the street to shake hands with them, and tell them of the accident. I then got the most frightful pains in the thick portion of the calves of my legs, and went to seek Medical aid. I was desired to keep quiet, and go to bed, and was prescribed for. I never slept all that night, and the effort to recall that painful time is exceedingly trying, as it still seems to be an unsupportable horror to me. I slept none, fidgeted about my bed in a purposeless way, longing for day to break till I could go down and see the smash. Shortly after four a.m., I dressed and washed without feeling at all refreshed, and went to see the accident, when I made a sketch of it. I came home about eight a.m., re-dressed myself, and had breakfast; the calves of my legs were frightfully painful, whether I walked or sat. Nevertheless, I went up to the hospital with a Medical friend to see the sufferers. I recollect his chaffing me about my idiotic way of walking and lifting my feet *frantically* high to go over a pebble, and then immediately afterwards stumbling over a curbstone or some large object. I couldn't stay quiet, but wandered about the hospital, behaving in a very unreasonable way, and felt dreadfully quarrelsome. I then had for three days a feeling of not having slept for *several years*, although I don't recollect lying awake all night. The bladder became very irritable, and on one occasion, in the middle of the day, a week after the accident, I passed the immense quantity of 75 ounces of urine, although I had emptied the bladder only two hours before. The quantity was determined in a very curious way. A friend insisted on my dining with him that day, although I had intended dining at home, and I felt so quarrelsome and out of temper that after dinner I had to make an excuse to retire to make water. Though I did not feel as if I was passing a large quantity, yet on measurement it was found as I have mentioned. Three days after the accident the feeling of an iron band being made tighter and tighter, and a general lightness of the head in moving about, with the most excruciating cramps in the muscles of the neck, particularly the longus colli and sterno-mastoids, in which latter pair of muscles I still get severe cramps if I keep my head long in any one position, especially stooping. You may have noticed my fidgety manner when speaking to people lately; when you see me in that way, you may know that my cramps are on. They seem to begin in the *middle* of the muscle, and gradually extend with increasing pain to their origin and insertion, becoming more painful at the latter place. I felt greatly depressed and out of spirits, and hated light, which was most acutely painful to me, and the least noise was like thunder. Unfortunately the walls of my house were very thin, and what I endured from a piano during my illness I could not give you the least idea of. My speech got very bad, and I constantly transposed the beginning and ending of words in the most extraordinary way, particularly words requiring the use of the tongue and the incisors—such a word as *distinct*, for instance; the letter *s*, either alone or in company, completely floored me. The copious urine lasted for three weeks, and for months after I could not pass my water freely at once without waiting for some minutes, and it became very painful to the urethra and bladder; indeed, I could often have cried from the pain of scalding urine. My dorsal vertebræ were very tender, and uncomfortable to lie on. Rough ground or loose stones cost me the most frightful agony. To this day I cannot comfortably carry on a long conversation without feeling fatigued and pumped out, with a sort of cloudiness or forgetfulness of what has been the subject of conversation. I nearly lost the art of spelling, and still have to use a dictionary. Noises bore me still, especially gratuitous ones, such as people shuffling with their feet, &c., &c. I feel myself that even now I am not the same man as I was. I have not yet recovered my colour or my weight; from being nearly 12 stone at the time of the unfortunate accident, I fell to 8½ stone."

The evidence of the Medical gentleman who treated him must be endorsed as having been correct, when he stated "that it was hard to say how his affection would terminate, that he was not fit for business, and that he could not undertake when he would be so."

A remarkable condition of the interior of the eye was also observed and attested to at the trial (which is further illustrated in another case which I have had lately under treatment). "On the right side the optic was congested and vascular, on the left there was a partial wasting, the effects being ultimately to impair sight."

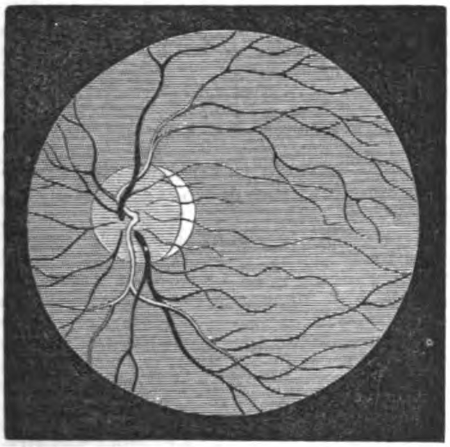
In this interesting case, where the sensations have been plainly recorded, evidently a spinal and cerebral concussion was received. At the time of the accident the body was thrown back from the sitting and leaning forward posture, against the back of the carriage, and the back of the head received a severe blow.

It is nearly two years since the receipt of this injury; yet, although it was endeavoured to be urged on the jury that the symptoms complained of were "gross exaggerations," I can testify from my own observation and acquaintance with this gentleman long before the accident that he has suffered severely, and has still not recovered from the effects of his ill-starred railway journey, for which he was awarded a miserable compensation indeed. In the foregoing case both pupils were dilated for months, and the general muscular cramps were of a distressing nature.

The succeeding history of a patient under my care during the last few months presents features of interest and of contrast.

A railway porter, æt. 30, married, father of three children, strong and wiry, who had been in the employment of the company as general workman. While engaged, in the middle of last December, shunting trucks, was struck on the left shoulder by one which had been set in motion by a fellow workman. It was not moving swiftly, but was heavier and less springy than passenger carriages. He was a good deal hurt, and staggered at the time, and there was considerable local bruising and extravasation of blood. He did no work for the next two days, but then went back for three or four days to complete his fortnight, when he had to give up; and from that date, he states, has not been able to "work a stroke," but has been miserable.

On coming under my observation (November) he presented a pitiable appearance. His entire muscular system was in a state of tremor. He could not hold a cup of water in his hand, but would let it fall; he could not support himself without effort and without great difficulty, owing to the vacillating and unsteady condition of his muscles. A student had to walk at each side of him and give him support while he made his walking efforts; his saliva was inclined to dribble; the pupil of his right eye was largely and permanently dilated; his speech was thick and his tongue clumsy,—on counting to twenty he was puzzled to say eleven, thirteen, and sixteen; he had formication of the hands and fingers, very slight in the feet, but they were hardly numb; even when he was lying, the tremulous condition of the muscles was remarkable; the temperature on both sides was equal and normal; he passed rather larger quantities than natural of urine; the pulse was quick and small, the appetite poor. He was much distressed about his condition, and was positive that on the day of the accident he was as "sound a man" as ever he was in his life. In conjunction with Dr. Jacob, a careful ophthalmoscopic examination was made of the eyes; the right eye, which presented the permanently dilated pupil, gave the following remarkable appearances, which, bearing in mind the report of the ophthalmoscopic examination of the previous case, is of importance. The general fundus of the eye was natural but slightly anæmic, and the blood-vessels were normal, except at the external side of the optic pupilla, where they were much reduced in calibre and wasted in appearance. The optic pupilla presented, as delineated in the accompanying illustration, a crescentic development of atrophy on the internal margin, but showed no cupping or other glaucomatous appearance. As the physical signs indicatad the commencement of atrophic disorganisation the prognosis was unfavourable.



◆

CASES OF RETAINED PLACENTA ILLUSTRATIVE OF THE METHOD OF REMOVAL BY COMPRESSION.

By Dr. McGuire, Cong, Co. Mayo.

In diverging in this paper from my botanic investigations into the Flora of Cong, I may perhaps aptly quote the line from Virgil—"Non omnes arbusta juvant, humilesque myricae."

I have found the above-named method, which was first proposed by Dr. Simpson, of Edinburgh, so successful for many years in my practice, that I hope the publication of the following few cases will not be without interest to some of your numerous readers.

Case I.—On the 24th ult., on visiting Mrs. C., æt. 30, a multipara, I found that she had, nine hours before my arrival, given birth to a full-grown living male child, which to my surprise I found to be still unseparated from the mother. (Many country midwives never separate the child till the after-birth comes away, and in the meantime the life of the mother or child, or the lives of both are lost.) The case in this instance was more favourable, for both lives were saved. My first operation was to separate the child in the usual way. On making an examination I found that the os was much contracted, that the uterus itself was soft and flabby; but still that its contour could be felt through the parietes of the abdomen. I grasped it firmly with both hands, and by thus applying an evenly compressing force upon nearly the whole of its external surface, I aided and imitated the natural action of the organ, and, in two minutes, I had the placenta and membranes expelled without applying any traction whatever to the cord.

Case II.—Some months ago I was called upon to attend a Mrs. M., æt. 35, a multipara. She had given birth to a living full-grown female child twenty-four hours before my arrival. It was, however, then dead, but, as in the former case, lay beside the mother unseparated from her. The os had so contracted that I could hardly introduce two fingers; the womb felt tolerably hard and globular. I formed the fingers of the right hand into a cone, as directed by Dr. F. Churchill in his excellent "Manual on Midwifery," and made them act as a wedge to dilate the os; while with the left hand I firmly grasped the womb, and in a few minutes succeeded in expelling its contents. The mother recovered without exhibiting a bad symptom.

Case III.—Mrs. R. Joyce, of Ballyveean, had been delivered of a living child at midnight. The nurse in this case, finding that the after-birth did not come, separated the child, and sent for me about seven hours after the birth. This was a more untoward case than either of the others, for, the placenta having partially separated at its margin, flooding was profuse, and the patient was *in extremis* from that cause.

The Rev. Mr. O'Rorke, P.P., had just administered the last rites of the church, and he and the friends had given up all hope of the patient's recovery.

My first act was to introduce the right hand as a plug to restrain flooding; on reaching the os I found that it had contracted to a very small compass. I gradually succeeded in introducing the points of all the fingers, and by the cone shaped wedge so formed I dilated the os considerably, while with the left hand, by friction and pressure on the abdomen, and finally by compressing the contracting womb, I squeezed out its contents. The patient made a good recovery, and has since borne children.

Case IV.—On the 30th ult. I was called on to visit Mrs. C., who had been ill forty-eight hours in her first confinement. The os was fully dilated and the head in the pelvis, but all pains had ceased, and the rigid membranes had not yet broken. With some difficulty I succeeded in rupturing these. This operation, combined with ergot, not being successful in bringing on adequate labour pains, I delivered her with the forceps (Dr. F. Churchill's) of a living female child. The womb remaining inactive I squeezed it, as in the first case, between both hands; and, without making any traction on the cord, I expressed the placenta.

The only classes of cases in which I have found this method of compression to fail are—1. Retained placenta after miscarriage. 2. Where there are extensive abnormal adhesions between the womb and placenta. In these I know of no other successful method but that laid down by Dr. F. Churchill in the work referred to above, namely, to introduce the hand into the womb and cautiously separate the placenta with the fingers.

Extraction by this means when carefully performed, though painful to the patient and involving no small difficulty to the practitioner, is, I think attended with very little danger; for, during a tolerably extensive practice, extending over a period of thirteen years, during which time I had frequently to perform this operation, it was never followed by any bad results.

◆

LECTURES ON HUMAN ANATOMY (*a*).

By Walter Rivington, M.S., Lond., F.R.C.S., Eng.

Surgeon to the London Hospital and Lecturer on Anatomy at the London Hospital Medical College.

Lecture I. (*continued*).

Man's place in Nature—The Human Skeleton—The Vertebral Column—General Characters of a Vertebra—Transcendental Anatomy—Theory of Archetypes.

"In most cases upon the anterior and posterior laminæ of the arch are flattened, slightly projecting more or less oval, smooth surfaces or facets, which in the natural state are covered with a thin layer of cartilage, and come in contact and articulate (by synovial joints) with the corresponding surfaces of the immediately antecedent and succeeding

---

(*a*) These Lectures are not given word for word as they were delivered, but contain the substance of several courses. They are designed specially for the use of students and as an *introduction* to the systematic study of human anatomy. One or two preliminary lectures delivered in previous years have been omitted, as it has been considered advisable to plunge at once *in medias res*. An Introductory Lecture was published in the Medical Press and Circular on January 13th and 20th, 1869.

b

vertebræ." These correspond with the human articular processes, and have been called by Professor Owen "Zygapophyses," that placed on the front edge of the arch being the anterior zygapophysis, that on the hinder edge the posterior zygapophysis. As a general rule the latter have their faces directed downwards, overlying the upward directed anterior. Zygapophyses of the vertebra next behind. This is a useful rule to remember in ascertaining which is the front and which the posterior surface of a vertebra. Sometimes the posterior zygapophyses have their faces directed outwards, in which case the corresponding anterior zygapophyses look inwards.

These articular surfaces on the arch constitute a second mode, by which the vertebræ are united, and their size and conformation aid in regulating the amount of motion allowed between the component parts of the column. They are often entirely wanting when flexibility is more needed than strength, as in the greater part of the caudal region of long-tailed animals."—Flower's "Osteology of the Mammalia," page 13.

There are still two or three processes found on the vertebræ which must be mentioned. A process, either single or double, grows occasionally from the under surface of the body, and has received the name of Hypapophysis. This process is found on the cervical or caudal vertebræ of some of the mammalia, and on the anterior lumbar vertebræ of the hare.

Lastly, there are two accessory processes connected usually with the articular processes or zygapophyses of the vertebræ, one with the anterior zygapophysis, called Metapophysis, and the other with the posterior zygapophyses, and called *Anapophysis.*

To render the foregoing account more clear, I will place side by side the scientific names and the corresponding parts of the human vertebra :—

Human Vertebra.	Ideal Vertebra.
Body	Centrum.
Arch	Neural Arch.
Two pedicles Two laminæ	Neurapophyses.
Spinous process	Neural Spine.
Articular processes	Zygapophyses.
Transverse processes :	
(*a*) Anterior	Parapophyses.
(*b*) Posterior	Diapophyses.
Ribs, and modified ribs	Pleurapophyses.
Processes, or tubercles found on superior articular processes of some vertebræ ...	Metapophyses.
Processes, or tubercles found on inferior articular processes of some vertebræ ...	Anapophyses.
Processes growing from the under surfaces of the bodies of some vertebræ in the lower animals ...	Hypapophyses.
Processes growing from the spinous processes of some vertebræ in the higher apes ...	Hyperapophyses.

The hœmal arch formed of the hœmapophyses, and supporting the hœmal spine, is absent in the human vertebra, but here the inspiration of the poetic anatomist achieves one of its greatest triumphs. Truly he says these parts are absent from the vertebra itself, but they are present nevertheless. In the dorsal region, for example, these parts have become greatly developed and attached to the extremities of the ribs, or pleurapophyses. The cartilages of the ribs are the hœmapophyses; and the segments of the sternum are the hœmal spines. The ribs, or pleurapophyses, and the costal cartilages, or hœmapophyses, and the sternum, or hœmal spine, form together a great hœmal arch or thorax, specially modified in the highest vertebrates, to enclose and protect the central organs of the circulationt, the heart, the aorta, and the great bloodvessels of the system.

There is something captivating in these speculations, and there is a basis of truth underlying some of those speculations which seem the most fanciful and farfetched. But the extravagant extent to which these views have been pushed, the torture to which some of the parts of the body have been subjected in order to extract from them a resemblance to a vertebra, has naturally given rise to the formation of another school of anatomists who refuse to advance farther than obvious resemblances will warrant. This school, of which Professor Huxley is the chief representative in England, as Professor Owen is of the Transcendental School, takes its stand chiefly on the mode of development of a part as the test of its affinities, and have received the name of the Developmental School. The transcendentalists say that the skull is made up of four vertebræ, and they find representatives of the parts of the ideal vertebra in the various bones of the skull. The developmentalists say that most of these resemblances are fanciful. The parts differ in appearance from vertebræ, and the history of their development shows that at no time did they exhibit any similarity to vertebræ.

Without pretending to pass any *cathedral* judgment on these rival views, I may be permitted to say that the transcendental theory has always appeared to me to be wanting in one of the great features of a successful generalization. The physical philosopher compares a number of objects of the same kind in order to ascertain what are their essential parts and features, and when he frames his definition of the object he embodies only those characters which are distinctive of it, essential and universal rejecting those which are accidental and inconstant. The transcendental anatomist compares a number of vertebræ, and culling from all quarters special and limited modifications, adds all these peculiarities to the essential features of the vertebra, and thus frames his ideal vertebra, and having framed it, he exercises his ingenuity in discovering resemblances to the parts of his ideal vertebra in arrangements apparently having a totally different character. The vertebra of the transcendentalist is therefore a vertebra which has no existence in the universe, it is entirely a conception of the anatomist, which transcends the limit of human discovery and experience. But the transcendentalist does not stop at the vertebra. He aims at forming a body which shall represent the archetype of all the vertebrate creation. Hitherto he has arrested his steps at the skeleton ; he has not ventured on furnishing it with soft parts or with internal organs. This archetype as it stands is "a faultless monster which the world ne'er saw." Without intending to treat it with any disrespect, it seems to me to be a philosophical toy—an anatomical puzzle. It reminds one of the description quoted as an example in the old Latin grammar—

> "Monstrum horrendum informe ingens cui lumen ad emptum."

As the Mammalian Orders are often referred to in these lectures it will be convenient to subjoin the following :—

CLASSIFICATION OF CLASS MAMMALIA (FLOWER).

SUB CLASS.	ORDER.		EXAMPLES.
1. Ornithodelphia	Monotremata	Two genera ..	Echidna, Ornithorhynchus.
2. Didelphia ..	Marsupialia	.. .. ..	Kangaroo, Opossum, Wombat.
3. Monodelphia ..	Edentata ..	.. .. ..	Sloths, Armadillos, American Anteaters, Pangolins, Cape Anteaters.
	Sirenia ..	.. .. ..	Manatus, Dugong.
	Cetacea ..	Mystacoceti ..	Whalebone, Whales.
		Odontoceti ..	Cachalots, Narwhals, Dolphins, Porpoises.
	Ungulata ..	Artiodactyla "Even toed"	Swine, Camels, Ruminants.
		Perisso-Dactyla "Odd toed"	Horse, Tapir, Rhinoceros.
	Hyracoidea	One genus ..	Hyrax.
	Proboscidia	Two species of Elephant only.	
	Rodentia ...	.. .. ..	Hare, Rat, Guinea Pig, Squirrel, Porcupine, Beaver, &c.
	Carnivora ..	Terrestrial or Fissipedia	Cats, Dogs, Bears.
		Aquatic, or Pinnipedia	Seals, Walrus, Sea Lions.
	Insectivora	.. .. ..	Hedgehogs, Moles, Shrews.
	Chiroptera	.. .. ..	Bats.
	Primates ..	.. .. ..	Lemurs, Monkeys, Apes, Man.

(*Conclusion of Lecture I.*)

The Medical Press

FORTNIGHTLY RETROSPECT

OF

MEDICINE, SURGERY, AND THE COLLATERAL SCIENCES.

> "The multiplicity of subjects with which the mind of the Medical man, who attempts to keep pace with the progress of his science, is constantly occupied renders it desirable that ideas which are intended to be of practical utility to him should be submitted to his grasp in the smallest compass and most defined form of which they are capable."

No. I.

N.B.—Authors are invited to send copies of their works, with such passages marked as they deem worthy of special notice in these Reports. All communications should be addressed to "The Editor of the *Medical Press Retrospect*," at either of the Offices of MEDICAL PRESS AND CIRCULAR.

(All rights in connection with these Reports are reserved.)

PHYSIOLOGY.

PHYSIOLOGICAL CHEMISTRY.

FALCK.—"The Physiology of Chloride of Sodium." *Virchow's Archiv.*, Vol. 65, Heft. 3.

HISTOLOGY.

GASSET, JOSEPH.—The *Gaz. Med. de Paris*, Jan. 4th, 1873, contains an interesting contribution to pathological histology from the pen of M. Gasset, in which he considers the histological phenomena of inflammation, and advances a new theory based on the consideration of molecular granulation.

GILLETTE.—"Description and Structure of the Muscular Coat of the Œsophagus in Man and animals." *J de l'Anat. et de Physiol.*, Nov.-Dec., 1872.

ORGANS OF LOCOMOTION.

HEITZMANN, C.—"Researches on Bone and Cartilage." *Stricker's Medicinisch Jahrbucher*, 1872, Part 4.

BLOOD.

MALASSEZ, M.—"Number of Red Globules of the Blood in Mammals, Birds and Fishes." *Acad. des Sci.*, December 2nd, 1872.

STRUVE, H.—"Two Different Blood-colouring Matters." *Virchow's Archiv.*, Vol. 65, Heft. 3.

REISS, L.—"Pathological Anatomy of the Blood." *Reichert und Du Bois-Reymond's Archiv.*, 1872, No. 2, Heft. 2.

PODOLINSKI, S.—"Expulsion of Carbonic Oxide and Nitric Oxide from the Blood." *Pflüger's Archiv. für Physiol.*, Band. 7, Heft. 2.

NUTRITION AND GROWTH.

WEISKE-PROSKAW, H.—"Influence of the Earthy Phosphates of Food on the Composition of Bones." *Zeitschrift für Biol.*, Band. 8, Heft. 2.

VOIT, C.—"Nutritive Value of Gelatine." *Zeitschrift für Biol.*, Band. 8, Heft. 3.

JOSEPH, H.—"Influence of Nerves on Nutrition and Growth." *Reichert und Du Bois-Reymond's Archiv.*, 1872, No. 2, Heft. 2.

HOFMANN, F.—"Passage of Fat into the Cells of the Body." *Zeitschrift für Biol.*, Band. 8, Heft. 2.

SECRETION AND EXCRETION.

AUBERT, H.—"Excretion of Carbonic Acid by the Skin in Man." Dr. Aubert estimates with his apparatus the quantity eliminated in twenty-four hours at a maximum of 97 grains, a minimum of 35·5 grains, and a mean of 60. *Pflüger's Archiv.*, Band. 7, Heft. 2.

LIEBERMEISTER.—"Elimination of Carbonic Acid on Exposure to Cold." The author contends that immersion in a cold bath temporarily augments the heat of the body, and that the amount of carbonic acid eliminated is approximately proportional to, and is an approximate measure of, the amount of caloric generated. *Deutsches Archiv. für Klinisches Medicin.*, Band. 10, Heft. 4.

WEISKE-PROSKAW, H.—"Varying Composition of the Urine on a Purely Animal Diet." *Zeitschrift für Biol.*, Band. 8, Heft. 2.

INNERVATION.

"Functions of the Cerebrum." Leading article in *Lancet*, Jan. 4th, 1873.

QUINCKE, H.—"Physiology of the Cerebro-Spinal Fluid." *Reichert und Du Bois-Reymond's Archiv.*, 1872, No. 2, Heft. 2.

LEGROS ET ONIMUS.—"Experimental Researches on the Physiology of the Pneumogastric Nerves." *J de l'Anat. et de Physiol.*, Nov.-Dec., 1872.

HERMANN, L.—"Galvanic Condition of Nerves during Electrical Stimulation." *Pflüger's Archiv. für Physiol.*, Band. 6, Heft. 2.

ORGANS OF SENSE.

ROBINSKI, D.—"The Anatomy, Physiology, and Pathology of the Lens in Man and Vertebrates." *Reichert und Du Bois-Reymond's Archiv.*, 1872, No. 2, Heft. 2.

EMBRYOLOGY.

WEIL, C.—"Fecundation and Development of the Ovum of the Rabbit." *Medicinische Jahrbücher*, Vol. 1, 1873. Weil thinks that the spermatozoa penetrate the germ and then vanish completely, and that the intimate union of the spermatozoa with the ovum constitutes the most important part of fertilisation and is explicative of the inheritance of faculties from the father. See Dr. Klein's analysis of the paper in the *Medical Record*, Jan. 8th, 1873.

MEDICINE.

GENERAL DISEASES.

SCHUPPEL.—"On the Identity of Tuberculosis with Variola." *Archiv. für Path. und Physiol.*, T. 56, Fasc. 1 et 2.

THAON.—"On the Nature of Tuberculosis." *Mouvement Med.*, Nov. 30th, 1872. See Dr. C. R. Drysdale's translation in *Med. Press Circ.*, Jan 1, 1873.

JONES, C. HANDFIELD.—"Cases of Anomalous Rheumatism." *Med. Times and Gaz.*, Jan. 4, 1873.

MORBID STATES OF THE BLOOD.

VIICHOW, in his recent work, "*Ueber die Chlorose und die dametzusammhängenden Anomalien im Gefassapparate*," calls attention to certain vascular abnormalities in cases of chlorosis. The heart and aorta were less developed than normally in most of the cases examined by him. He thinks also that the deficiency of the vascular system and of the blood induces abnormalities of the ovaries and uterus, thus accounting for the connection between chlorosis and disturbances of the menstruation. He indicates how the defective development predisposes to various diseases, more especially to early fatty degeneration of the heart and aorta. The work is very carefully analysed by Dr. Berkhart in the *Med. Record*, Jan. 8th, 1873.

MOSLER.—"On the Etiology of Leucæmia." *Archiv. für Path. et Physiol.*, T. 56, Fasc. 1 et 2.

HANOT recently reported to the *Soc. de Biologie* a case in which uræmia, occurring in a paralytic patient, was distinguished from cerebral hæmorrhage and softening by means of the thermometer, in accordance with the rule laid down by Dr. Bourneville, that in uræmia the fall of temperature is considerable. The case is noticed in the *Lancet*, Jan 4th, 1873.

Davaine et Boulay have lately been directing the attention of the *Acad. de Med.* to the subject of Septicæmia. See recent Nos. of the *Bul. de l'Acad. de Med.*

Perrin has written some interesting papers on the same subject. *Gaz. Hebd.*, Nos. 47 and 51, 1872.

Lewis, T. R.—Dr. Lewis has discovered that in the blood and urine of persons suffering from chyluria in tropical climates a hæmatozoon, apparently belonging to the Filaridæ, exists. Appendix E., *Report of the Sanitary Commissioner in India*, 1872. See also Dr. Cobbold's analysis of the paper in the *Medical Record*, Jan. 8th, 1873.

FEVERS.

Williams, C. Theodore.—"The Treatment of Pyrexia in Phthisis by Cold Baths." *Clin. Soc. London*, Dec. 13, 1872. Cases in which the pyrexia had persisted and assumed a type sufficiently well marked to afford a characteristic tracing were the subjects chosen. Dr. Williams claims for the cold bath that, in his cases, it did no harm, that the appetite was improved, weight was gained, sleep was induced, and the temperature lowered for a time. He would not urge the employment of the cold bath, however, except in very obstinate cases.

Crociani, in a paper in *L'Imparziale*, Dec. 16, 1872, advocates the employment of iodine and flour of sulphur instead of quinine in the treatment of intermittent fever.

DISEASES OF THE ORGANS OF CIRCULATION.

Whipham, T., relates a case in which an old blood clot adherent to the wall of the left ventricle and septum of the heart produced thickening of the endocardium and degeneration of the muscular tissue. The case presented two unusual complications—extensive thickening of the endocardium beneath and around the clot, and atrophy of that portion of the walls to which it was attached. *Lancet*, Jan. 4th, 1873.

Heiberg.—"On Ulcerative Endocarditis, with Fungoid Growth in the Heart." *Virchow's Archiv.*, Vol. 61. See Dr. Payne's analysis of the paper in *Medical Record*, Jan. 8th, 1873.

Yeo, Gerald, puts on record a case in which hypertrophy of the right ventricle and atheroma of the pulmonary artery were developed in an extreme degree. He considers that the co-existence of these affections in the same individual establishes a relation between them. *Path. Soc. Dub.*, Dec. 14th, 1872.

DISEASES OF THE ORGANS OF RESPIRATION.

Cockle, John.—"Intermittent Cervical Hernia of the Lung." *Med. Times and Gazette*, Jan. 4th.

DISEASES OF THE ORGANS OF DIGESTION.

More, James.—Dr. More places on record a case of Sarcina Ventriculi. *Lancet*, Jan. 4th.

DISEASES OF THE LIVER.

Whitmore, W. B.—"Suppurating Hydatid Cyst of Liver treated by Puncture—Recovery." *Lancet*, Jan. 4th.

DISEASES OF THE SPLEEN.

Stokes, W., brought under the notice of the *Path. Soc. Dub.*, Dec. 14th, 1872, a case of strumous affection of the spleen and spinal cord. The case presented some of the symptoms of cerebro-spinal arachnitis, but there was no fever. The spleen was found to be the seat of a cyst, with ossific plates involved, and containing mortar-like matter.

DISEASES OF THE PERITONEUM.

Lyons, Robert.—In an interesting paper by Dr. Lyons, read before the *Med. Soc. Coll. Phys. Irel.*, Dec. 11th, 1872, he advocated *early* tapping as a valuable means of affording relief from the distressing symptoms of ascites.

DISEASES OF THE KIDNEYS.

Clark, Andrew.—"On Renal Inadequacy." *Medical Times and Gaz.*, Jan. 4th.

Macswiney.—"Dilatation of the Kidneys, &c., consequent on Stricture." *Path. Soc. Dub.*, Dec. 14th, 1872.

Johnston, G.—"On the Pathology, Diagnosis and Treatment of Bright's Disease." *Brit. Med. Journ.*, Jan. 4th, 1873.

DISEASES OF SUPRA-RENAL CAPSULES.

Rosenstirn.—"Analysis and Semeiology of the Urine in Addison's Disease." *Archiv. für Path. und Physiol.*, T. 56, Fasc. 1 et 2.

DISEASES OF THE NERVOUS SYSTEM.

Latham, P. W.—"On Sick Headache." *Brit. Med. Journ.*, Jan. 4th. Dr. Latham contends that sick headache is a nervous disorder, but an affection of the sympathetic system rather than a neuralgia, as Dr. Anstie believes. Dr. Latham's paper is a very exhaustive one, and is a complete *resumé* of the literature of the subject.

Raggi, Antigono, writes an important paper on the relations existing between diseases of the heart and mental diseases. *Bull. del Scienze Med.*, Nov. 1872.

MISCELLANEA.

We would call attention to a very ingenious contrivance described by Dr. Poore before the *Clin. Soc. Loud.*, Dec. 13th, for intensifying cardiac murmurs and other sounds produced within the chest.

"The Ophthalmoscope as an Aid to Diagnosis" is the subject of a valuable paper by Dr. Joy Jeffries in the *Boston Med. and Surg. Journ.*, Nov. 7th, 1872, and given in abstract in *Med. Times and Gaz.*, Jan. 4th, 1873. He alludes to the value of the instrument as a means of diagnosis in mania and dementia, in tubercular meningitis, in meningitis with fever, in hydrocephalus, in intra-cranial tumours, in general paralysis, in affections of the spinal cord, in failure of sight, in Bright's disease, in diabetes, in poisoning from alcohol, tobacco, or lead, in affections of heart or blood-vessels, and in diseases of the eye itself.

SURGERY.

PROCESSES OF LOCAL DISEASE.

Savory, W.—"Erysipelas: Its Nature and Treatment." *Brit. Med. Journ.*, Jan. 4th.

Hulke, J. W.—"Rodent Ulcer." *Med. Times and Gazette*, Jan. 4th.

INJURIES AND DISEASES OF BONES.

Poncet.—Attention is directed by M. Poncet's communications on this subject to the *Gazette Hebd.*, Nos. 42, 46, and 49, 1872, and *Lyon Med.*, Dec. 22, 1872. See Mr. Beck's report in *Med. Record*, Jan. 8, 1873.

INJURIES AND DISEASES OF JOINTS.

Bellamy, Edward.—"Case of Dislocation of the Patella on its edge, the Outer Surfaces looking Outwards." *Brit. Med. Journ.*, Jan. 4th.

INJURIES OF NERVES.

Dalby, W. B.—"Case of Wound of Portio-dura causing Facial Palsy." The patient a little child, had accidentally thrust a pair of sharp-pointed scissors into his left ear. *Clin. Soc. Lond.*

INJURIES OF THE HEAD.

Kidd, Abraham.—"Case of Extensive Compound and Comminuted Fracture of the Skull." The following were the points of interest: The advanced age of the man (60); the extremely extensive nature of the fracture; the loss of much brain substance; and the almost perfect recovery, except that vision in the right eye was impaired. The patient has no recollection of having received any injury. *Irish Hosp. Gazette*, Jan. 1.

Pemberton, Oliver.—"Case of Compound Comminuted Depressed Fracture without Symptoms—Elevation and Removal of Fragments—Recovery." *Lancet*, Jan. 4th, 1873.

Bennett, E.—"Case of Fracture of Base of Skull caused by a Fall on the Head, and probably resulting from Impaction of the Vertebræ against the Condyles." *Path. Soc. Dub.*, Dec. 14th, 1872.

INJURIES AND DISEASES OF THE EYE.

Snellen.—The *Brit. Med. Journ.*, Jan. 4th, contains a description of Mr. Solomon's method of treating entropion according to the plan originated by Dr. Snellen, of Utrecht.

Bougon records a case of ciliary blepharitis, with consecutive entropion, complicated with central leucoma of the two corneas. *Mouv. Med.*, Dec. 21, 1872.

Hutchinson, Jonathan.—Mr. Hutchinson, in an important paper, *Lancet*, Jan. 4, draws attention to a peculiar form of iritis occurring in the children of gouty patients. He describes it as differing from the common types of iritis in being insidious, for the most part painless, and persistent rather than paroxysmal. He suggests that, as regards the study of gout and rheumatism, the eye offers a field of unusual interest, and that we shall find in the raneitis of arthritic inflammation to which it is subject a solution of many doubtful questions. He concludes an eminently suggestive paper by maintaining that a "tendency inherited from parents who have suffered from true chalkstone gout may produce in their offspring inflammatory phenomena which differ widely from the usual characters of gout, and are unattended by deposit of lithate of soda."

Wilson, Henry.—"Cases Illustrative of Sympathetic Ophthalmia." *Irish Hosp. Gazette*, Jan. 1.

Jacob, Archibald.—At a meeting of the *Surg. Soc. Irel.*, Nov. 29th. Dr. Jacob brought forward a beautiful specimen of melanotic sarcoma of the cornea. "Removal of Cataract by Solution." *Medical Press and Circ.*, Dec. 18, 1872.

AFFECTIONS OF THE FACE, NOSE, PALATE, &c.

Dauvergne.—"On the Employment of Iodised Caustic Solution of Lugol to Prevent the Reproduction of Naso-Pharyngeal Polypi."

Erichsen, J. E.—"Necrosis of Body of Sphenoid—Removal of the Whole Body through the Mouth—Recovery." *Med. Times and Gazette*, Jan. 4.

Best, A. Vans.—"On Diseases of the Antrum." *Lancet*. Jan. 4.

AFFECTIONS OF LARYNX.

Durantz, E. N.—"On Soft Tumours of the Larynx." *Med. Soc. Lond.*, Dec. 9, 1872, *Medical Press and Circ.*, Dec. 25, 1872.

James, Prosser.—"Clinical Illustrations of Diseases of the Throat and Lungs." *Medical Press and Circ.*, Dec. 18, 1872.

INJURIES AND DISEASES OF THORAX.

Rasmussen, Vald. — "The Employment of the Aspirator in Pleuritis with Effusion" is the subject of an interesting communication to the *Irish Hosp. Gazette*, Jan. 1. Dr. Rasmussen strongly advocates the employment of capillary thoracentesis with aspiration in cases of pleuritis with effusion, and also in suitable cases of ascites, ovarian cysts, echinococcus cysts, spina bifida, arthritis of knee, chronic and acute, and in cases of congestion-abscesses, simple abscesses, and suppurating adenitis.

We may here allude to a case occurring in the practice of Dr **Harris**, at St. Bartholomew's Hospital (*Lancet*, Jan. 4), in which emphysema was greatly relieved by paracentesis thoracis. Two cases of paracentesis thoracis are also reported in *Med. Times and Gazette*, Jan. 4, as occurring under the care of Dr. **Peacock**, of Victoria Park Hospital.

INJURIES AND DISEASES OF ABDOMEN.

MacDowell, Benjamin.—"Penetrating Wound of Abdomen—Extrusion of a Portion of the Great Omentum—Recovery." This case Mr. MacDowell considers as confirmatory of the opinion that the peritoneum, while it should not be meddled with unnecessarily, is not so much to be dreaded as surgeons were formerly wont to suppose. *Med. Press and Circ.*, Jan. 1.

HERNIA.

Duhamel.—"Voluminous Congenital Exomphalos." *Gazette Med. Strasbourg*, Dec. 1, 1872.

DISEASES AND INJURIES OF URINARY ORGANS.

Stokes, W.—Professor Stokes reports a most interesting case, *Irish Hosp. Gazette*, Jan. 1, in which an entire gum elastic catheter was removed from the bladder by Allarton's median operation. The patient was in the habit of practising auto-catheterisation for an old-standing stricture, and while in a fit of intoxication the instrument passed up into the bladder. Professor Stokes claims for this case three points of interest—the unusual nature of the foreign body, the difficulties of the operation, owing to a two-fold stricture and great induration of the peritoneum, and, lastly, he supposes that it shows that the vermicular action of the urethra is towards, and not from, the urethra.

Loustan's work, "On the Urinary Passages," in which he considers the subject of divulsion of strictures of the canal of the urethra, is now published.

AFFECTIONS OF THE EXTREMITES.

Jessop, T. R.—"Case of Tumour in the Thigh closely resembling Aneurism—Treatment by Antiseptic Ligature of Common Femoral Artery—Death in sixteen weeks afterwards from Gangrene." *Lancet*, Jan. 4.

Morgan, J.—"On a Peculiar Affection of the Hands and Feet." *Med. Press and Circ.*, Dec. 16, 1872 and Jan. 8th, 1873. We have no hesitation in characterising this paper as a most valuable contribution to surgical literature.

MIDWIFERY.

Joulin.—The author revives the question, *Gazette de Joulin*, Dec. 15, 1872, as to whether it is necessary to support the perinæum during labour. The same author, in the same journal, writes on narrowing and malformation of the pelvis, and speaks of the repeated success of cephalotripsy.

DISEASES OF WOMEN.

Playfair, W. S.—The subject of intra-uterine medication is now attracting much attention; the *Lancet*, Jan. 4, contains the first part of a series of lectures on this subject by Dr. Playfair.

Atthill, Lombe.—"Endometritis" was the subject of a communication by Dr. Atthill to the *Dub. Obstet. Soc.*, Dec. 14, 1872, in which he advocates the application of fuming nitric acid to the interior of the uterus as a successful method of treatment.

Gallez, Louis.—Dr. Gallez has just published his "History of Ovarian Cysts" ("Histoire des Kystes de l'Ovaire envisagés surtout au point de vue du Diagnostic et du Traitement," Bruxelles, 1873).

Hebra.—"On some Affections of the Skin in Pregnant and Puerpural Women." *Wiener Medizinische Wochenschrift*, 1872, No. 28, quoted *Med. Times and Gazette* Jan. 4. Professor Hebra calls attention to the fact that the physiological changes in the uterus which accompany pregnancy may give rise to similar diseased conditions of the general surface as are met with in several pathological conditions of the internal female organs. He calls upon gynæcologists to investigate the nature of this connection between the skin and internal genitals.

DISEASES OF CHILDREN.

Sansom, A. E.—"Infantile Paralysis treated by the Continuous Current." *Med. Soc. Lond.*, Dec. 9, 1872.

MATERIA MEDICA AND THERAPEUTICS.

"Action of Mercury on the Liver." Leading article, *Brit. Med. Journ.*, Jan. 4. Calls attention to Schiff's experiments as proof that bile passes from the liver into the duodenum, thence part of it passes into the blood, and so to the liver again, while another part of it is carried down with the intestinal contents and evacuated with the fæces. It is assumed that mercury acts on the duodenum as a purgative, and thus prevents absorption there. The article will repay perusal.

Cleland, John.—"Guaiac in Ovarian Affections." *Irish Hosp. Gazette*, Jan. 1. Professor Cleland instances cases illustrative of the benefit derivable from guaiac in amenorrhœa and in inflammatory affections of the ovaries. He considers it to be useless in acute cases, and in those in which the primary disorder is in the uterus, neither has he seen much benefit from its use where there was any marked affection of the cervix. He orders it in 10 grain doses of the resin every morning, taking care to provide against the diarrhœa which is likely to be induced. The great value of guaiac in cases of persistent sore throat recalled to Professor Cleland's mind the old belief of a sympathy between the tonsils and the testes or ovaries, and thus he was led to experiment.

Papillaud et Mousnier.—"On the Employment of Arseniate of Antimony in the Form of Globules." *Scalpel*, Dec. 15, 1872.

Rabuteau et Papillon.—"On the Therapeutical Effects of Silicate of Soda." *Acad. des Sci.*, Dec. 2, 1872.

Picot.—"On the Anti-Fermentable Properties of Silicate of Soda." *Acad. des Sci.*, Dec. 2, 1872.

Lecoq.—"Thesis on the Physiological Properties of Chlorure of Sodium."

Byasson.—"Decomposition of Hydrate of Chloral." *Comptes Rendus*, Vol. 75, p. 1628, quoted *Pharm. J.*, Jan. 4.

Plancheon.—"On Striated Ipecacuanhæ." *J. de Pharm. et de Chim.* (4), 16, p. 404, quoted *Pharm. J.*, Jan. 4.

Colin.—Attention is directed to the very interesting work of Dr. Colin, entitled "Etude sur les Sels de Quinine."

Quinine has lately been found to be a powerful preventative of putrefaction and of alcoholic fermentation. C. Binz believes it to be capable of arresting putrefaction in the blood.

Fraser, Thomas R.—"On the Kombé Arrow Poison (Strophanthus) of Africa." *J. of Anatomy and Physiol.*, Vol. 7, quoted *Pharm. J.*, Jan. 4.

Transactions of Societies.

THE SURGICAL SOCIETY OF IRELAND.

The Society met on the evening of the 3rd January.

The President of the College of Surgeons, Dr. Kirkpatrick, in the Chair.

Dr. Chas. F. Moore submitted to the Society

THE LARYNX, PART OF THE TRACHEA, THE THYROID GLAND, AND TWO SMALL PORTIONS OF INTEGUMENT OF A MAN, ÆT. 27,

who was admitted on Dec. 28th last, under his care to Cork Street Hospital, where he had recently been under treatment for fever on two occasions. His head was much swollen and of a purplish colour, within twenty-four hours an eruption of variola came out on the wrists, legs, &c. Purpuric spots also appeared on the limbs and in large patches on the shoulders. He complained of his throat, he had ichorous discharge from the conjunctivæ and nails. He spat up some blood a short time before his death, which took place about thirty-six hours after admission to hospital. On examination, about thirty hours after death, the thyroid gland was found abnormally large, as were also the liver and kidneys, especially one of the latter. The spleen was soft. The aorta contained a large quantity, indeed was, when examined, full of dark blood. The heart contained large clots of fibrine interwoven through the corneæ columnæ of each ventricle. The lungs were much congested, and in some parts pneumonic. The larynx was greatly congested, the mucous membrane and subjacent tissues being injected, swollen, and of a deep red colour. The treatment adopted during this, his fatal illness, was mainly supporting the patient's strength with wine and such food as he could use, cataplasms to the throat, and some small doses of ipecacuanha, and Dover's powder. It appears that this man had been exposed to cold when in a state of copious diaphoresis, subsequently to his two recent attacks of fever.

Mr. Richardson inquired if the true vocal cords were engaged in the disease?

Dr. C. F. Moore replied that they were. By closing the larynx and trachea the specimen, even in its present state, showed a barely perceptible opening for respiration.

SMALL CALCULUS IN THE BLADDER.

Prof. Macnamara said that on etiological considerations he thought it desirable to present a small calculus that he removed on Monday morning last from the bladder of a boy, æt. 14. He had been suffering under the disease from his fourth year, and one of the remarkable symptoms was repeated hæmaturia. There was little in connection with the calculus to make it of importance as a recent specimen save on etiological grounds; because in this country it was remarkable how rarely compared with the population cases of calculus were met with. Some of the most eminent surgeons of this city, men having the largest practice, had not exceeded something like half a hundred cases. On searching over the records of the Profession here he found that Sir Philip Crampton had only had fifty-two cases, and on mentioning the matter to Dr. Fleming, that gentlemen said he thought Mr. Cusack had not many more. When he (Prof. Macnamara) was in Aberdeen, his valued friend, Mr. Keith, invited him to witness his 266th and 267th cases of lithotomy. Therefore, he thought, on etiological grounds, it was of importance that every case of calculus occurring in this country should be made as public as possible. He removed this specimen by the ordinary lateral operation. He might mention in connection with the late discussion on Ether *v.* Chloroform, that his colleague, Prof. Morgan, was kind enough to attend at the Meath Hospital and administer ether to this patient, and from the time the boy was placed on the operating table until he left it for his bed, twenty minutes did not elapse. The anæsthesia was most perfect, the respiration perfect, there was no sickness, and it was remarkable that the boy never complained of the smell or taste of the ether afterwards. This made a most favourable impression on his mind, and all but made him a convert to ether as administered by Dr. Morgan's apparatus.

VERMICULAR ACTION OF THE URETHRA.

Prof. Macnamara was desirous to make some observation on a subject that had engaged his attention for a great number of years. When he was a student, and for some years afterwards, he entertained the opinion which he had been taught in his youth that the vermicular action of the urethra was outward and not inwards—that when a foreign body was lodged midway in the urethra, the tendency of that body would be to make its way outwards and escape through the external meatus, and not to make its way back towards the bladder. However, very early in life circumstances arose which drew his attention to the study of cases of stricture, and shortly afterwards he began to doubt that which he had been taught, and which he was aware was still very extensively disseminated amongst the minds of the members of the Profession—viz., that the vermicular action of the urethra was outwards and not inwards. This was rather an interesting physiological question, and it had also an important practical bearing. In fact, it was exceedingly difficult to find any physiological problem the solution of which did not involve some practical interest. It might be interesting to trace the origin of what he believed to be the error, and that was the undoubted fact of a small calculus or a small portion of a large calculus became impacted in the urethra unquestionably the working of that calculus was outwards; but this he believed not by any means attributable to vermicular action, but to the *vis a tergo* from the rush of water. Many years since his attention was drawn to the fact that if a catheter was fastened in the urethra the tendency was to make its way towards the bladder and not to fall out. So thoroughly did he become impressed with the truth of this observation that when he was "docking" a patient—he meant when he introduced a gum elastic catheter into the bladder and fastened it there intending to leave it for twenty-four hours—he put on a jugum; but his object was not to prevent the catheter falling out but to prevent it going in, for he had more than once observed that a catheter placed in the urethra made its way towards the bladder, and in some cases on coming to his patient he had been rather startled at not seeing any portion of the catheter protruding from the *meatus externus*. He determined to make a practical application of the subject, and many years ago it became his practice when dealing with what he might call mixed strictures—partly organic and partly spasmodic—to pass a cat-gut bougie as far as he could towards the bladder and fasten it there, and on coming back two hours afterwards he would be rather surprised if it had not travelled on towards the bladder. He communicated these observations to his friends in the Profession many years ago. One remarkable case occurred during the period when Mr. Stokes was his colleague in the Meath Hospital. Mr. Stokes had a case of rather difficult stricture to deal with. He advised him to introduce a cat-gut bougie and lodge it in the stricture, and assured him his experience was that in a couple of hours he would find that the cat-gut had travelled towards the bladder. Mr. Stokes replied that the teaching of the school was opposed to this. However, he followed out his suggestion, introduced the cat-gut bougie into the stricture, and in two or three hours afterwards he was much gratified to find it was lodged in the bladder. He (Prof. Macnamara) believed that the fact—that an instrument had a tendency to work inwards towards the bladder—could only be explained on the principle of vermicular action. No doubt the vermicular action was feeble, and in the 60th or 70th part of a square inch of the urethra its force would be almost infinitesimal; but when an instrument was introduced for some five or six inches the vermicular action was exercised over the whole of this length, and was sufficient to work the instrument on by degrees until it entered the bladder. In the case of the little calculus which he brought forward that evening it afforded a very small surface for vermicular action, this force was quite ineffective against the *vis a tergo* when the patient attempted to empty his bladder; and this explained why the tendency of a calculus was outwards while the tendency of a catheter was inwards. Nothing was done in Nature without some great object; and he believed this was one of the securities intended by the Great Organizer of our system to prevent a leakage of the bladder—that in addition to the other securities against leakage we have this vermicular action by which a drop of water, if it leaked out into the urethra, was returned again, and it was that which preserved the cleanliness of the patient. He believed that this physiological fact was of great practical importance in the treatment of strictures. He was now in the habit whenever he met with an old stricture, which some persons call "impassable stricture," of treating it with the cat-gut bougie, and this mode of treatment had been repeatedly followed by the most satisfactory results. Having lodged the cat-gut bougie in the stricture he left it there, and his experience was, on going back in two or three hours, even in spite of the cat-gut swelling, it had advanced towards the goal he wanted it to reach. The swelling did not occur in the case of the small gum-elastic catheter which he also used. That instrument would gradually work down in the same manner; it had less resistance to encounter in the shape of swelling, but it afforded just the same surface for the vermicular action, and it would much more frequently reach the bladder than the cat-gut. There was an old saying that there was nothing new under the sun. Last night he laboured under the impression that the observations he had just made were original with himself; but he had the pleasure of meeting his friend Mr. Fleming at dinner, and on mentioning the matter to him he said that he had placed similar facts on record in the *Dublin Hospital Gazette* in 1858. It was a pleasure as well as a duty to say that he had been anticipated by Mr. Fleming in the observations he had made on this subject. Mr. Fleming used the remarkable expression that the urethra had, as it were, a "sucking power," and he also spoke of its vermicular action as operating in the same way, and these observation from an authority so much respected as Mr. Fleming who had done so much for surgery, especially in this department, encouraged him in making this statement, as excepting the paper of Mr. Fleming alluded to, he was not aware that attention had been drawn to this subject in any work on urinary diseases. He had looked over several of the standard works on the subject, and they contained not a word in reference to it; and if nothing more accrued from his observations than that they had rendered unto Cæsar the things that were Cæsar's, he thought he should not have wasted their time that evening.

Mr. Fleming said in reference to a case in which a catheter had to be cut out of the bladder, that it clearly showed the vermicular action was towards the bladder. It appeared to him in some cases as if the bladder were trying to swallow the catheter, so energetic was its action. Mr. Fleming called attention to the fact that sometimes the catheter disappeared, and he attributed this partly to vermicular action, and partly to the swelling of the glans-penis. He (Prof. Macnamara) had seen this occur without any swelling of the glans penis, the disappearance of the catheter being solely due to vermicular action, and this explained how frequently they were called upon to resort to operative interference in cases where the patient himself being probably drunk at the time introduced a gum elastic catheter, which, not being fastened, made its way towards the bladder and disappeared. He had seen in the Meath Hospital, under Mr. Porter, some two or three cases of this kind. Mr. Fleming had recorded several similar cases, and he believed it was not a suction power, but the vermicular action of the urethra being towards the bladder and not from the bladder which had led to these results.

The **President** endorsed Mr. Macnamara's views as to the great value of the cat-gut bougie, and thought the cases he had mentioned where the catheter had made its way into the bladder tended to confirm his theory.

Dr. Stapleton had had a great deal of experience for many years in dealing with strictures. A cat-gut bougie was passed into a stricture, and was caught there by spasm; a small piece of the cat-gut generally passed through the stricture, and the water from behind reaching this caused it to swell; the result was that it drew on the cat-gut a little bit more, and this also swelling drew on more, and in that way it made some progress towards the bladder. The same thing would occur with a catheter if not very well made, but if catheters were well made they would not swell or blister, or be drawn towards the bladder. As to Mr. Macnamara's theory of vermicular action he did not believe in it. He would like to know from Mr. Macnamara or Mr. Fleming if they had ever known the whole nine or twelve inches of a catheter to be drawn into the bladder, because what he had seen cut out of bladders were only pieces of either catheters or bougies. He had known more than one case when it was said a catheter had gone into the bladder, and when it was taken out after a great deal of trouble, it was found to be a piece of an old catheter, and not the bougie that had been recently placed in the patient. He remembered a case where a cat-gut bougie having been pushed in too far unluckily tied a knot on itself and there was a great deal of difficulty in getting it out because this knot had swelled to an enormous size. If it enlarged in one case it would in another, and he would expect to find that these cat-gut bougies, when left in the urethra two or three days, became enlarged behind the stricture, while they would not be enlarged in front of it. He repeated that he should like to know whether the whole of a catheter from the ivory handle of the instrument had ever been found in the bladder.

Dr. Henry Kennedy said that the first case recorded in the new Irish Medical journal which had just been published in this city, was that of a whole catheter which had passed into a man's bladder and which was cut out by Mr. Stokes, and so perfect was it that the plug was still in the mouth of the catheter.

Mr. Fleming said it was gratifying to hear the remarks which had been made on that occasion, as on the one hand they would teach them not to be too dogmatical in their opinions, and on the other, they proved the great advantages to be derived from discussions in that room. Mr. Macnamara's mode of treating stricture was to insert a cat-gut bougie and leave it in the stricture for a couple of hours, in the course of which he found that it gained ground in the stricture and made its way into the bladder. Now he should like to ask any gentleman present what would be the condition of that cat-gut after a couple of hours? Did he think because it yielded to his fingers that the cat-gut was going forward and that it got into the bladder? He (Mr. Fleming) was quite favourable to the introduction of the cat-gut bougie into the stricture, provided it was passed in as rapidly as possible into the bladder, as it was then in a condition not so yielding as if it had remained in the urethra for some time. He had repeatedly passed small bougies of different sizes, conical or otherwise, left them in while going the rounds of the hospital, and on returning to the patient after that short space of time found he was able to double the size of the instrument. This proved the value of gradual dilatation. Mr. Macnamara was mistaken in saying that he (Mr. Fleming) attributed the disappearance of the instrument to the enlargement of the glans penis. What he said was that in the majority of cases there was congestion of the whole penis, and that very congestion, with other causes would conceal the whole of the catheter in the organ, and assist in its advancement into the bladder. Mr. Stapleton asked who had ever seen a whole catheter of ordinary size within the bladder? He (Mr. Fleming) asked the same question. Mr. Stapleton was right in saying that in most of these instances the whole catheter was not in the bladder, but the greater part of it was lying in the dilated portion of the urethra behind the stricture. He had removed catheters supposed to be in the bladder, but the greater portion of them was outside in the track of the urethra. In the observations which he had published many years ago on this subject, he spoke of the "suction" of the bladder. Now he asked, had any gentleman ever introduced an instrument into the bladder in a case in which there was not some stricture or disease of the urethra? He assumed not, and that whenever either a catheter or bougie was introduced, the urethra was in a condition of disease. In such a case the instrument being not fully introduced, the water could not get away, the bladder became greatly distended, the ureters were also affected, and in that way there was a sort of suction power on the part of the bladder which assisted in drawing in the instrument.

Professor Morgan thought the term suction power of the bladder an ambiguous one. If the bladder and the ureters were full, he thought it would be difficult to exercise suction power. He also objected to the theory of vermicular motion put forward by Mr. Macnamara, and considered that the explanation of the phenomenon was to be found in the anatomical arrangement of the fibres of the accelerator urinæ muscle. It was not at all impossible that when an instrument was passed into the bladder, from the direction of the fibres we may have a reversed action of the muscle, and that may draw the instrument in towards the bladder, so far as that portion of the urethra was concerned. That explained why the instrument was drawn towards the bladder, but did not get into it, and neither the enlargement of the glans penis nor the vermicular action of the urethra would suffice to explain it. They knew when throwing an injection into the urethra, if the mouth be closed in order to retain the injection, the moment the finger was taken away the injection came out with considerable force. On the other hand, when a bougie or catheter was introduced, the action of the accelerator urinæ muscle might be reversed in consequence of the peculiar arrangement of its fibres.

Mr. Fleming never stated that the congestion of the glans alone would assist in the disappearance of the instrument; he meant the enlargement of the whole organ.

Mr. Wharton did not understand the observations of Mr. Fleming as to the suction power of the bladder, neither could he understand how vermicular action could produce the effect attributed to it by Mr. Macnamara. If a cat-gut bougie were got into a stricture and made its way into the bladder, that was no proof *per se* that it was the result of vermicular action. He could not see how the stricture would have the power of sucking in the instrument as had been suggested. If it were true that the usual action of the urethra was to draw the instrument into the bladder, he certainly would never be apprehensive that it would be forced out, and yet as a matter of practical experience they frequently found the catheter expelled from the urethra. Very lately he used a conical bougie in a case of stricture, but the instrument was forced out instead of being drawn in. He saw no explanation of the facts mentioned by Mr. Macnamara, except that given so clearly by Mr. Morgan. The action of the sphincter of the bladder itself had been somewhat overlooked. When an instrument was passed into the bladder, the contraction of the sphincter upon it might have the effect of drawing it into the bladder.

Mr. **Richardson** asked Mr. Macnamara how he explained the recourse, by the surgeon, to the use of the winged catheter—an instrument with a wing at either side a little behind the beak, which expanded when the catheter reached the bladder, and prevented it from coming out. With regard to the cat-gut bougie being forced on by the muscular action of the urethra, he would merely ask could the full-sized urethra in front of the stricture act on the small cat-gut bougie? Suppose a piece of catheter got wholly within the urethra, the natural musculo-elastic structure of this canal contracting either in front or behind it would drive it one way or the other without the necessity of our having recourse to the theory of a reversed vermicular action. He had over and over again seen a catheter pushed out from behind forwards, of the urethra by this musculo-elastic action.

Dr. **McDowell** considered that the pathological changes which the urethra must undergo to develope stricture would upset the theory of vermicular action. If a large quantity of lymph were shed to form the stricture how could the vermicular action of the urethra be intact?

Professor **Macnamara** replied. He stated that he had quoted accurately the words in Mr. Fleming's paper attributing the disappearance of the catheter to suction power of the bladder, vermicular action of the urethra, and tumefaction of the penis itself. Mr. Stapleton's denial that catheters had a tendency to advance towards the bladder was contradicted by his experience. There could be no question that instruments had gone towards the bladder, and he himself had seen two instruments which unquestionably were in the bladder. He wanted it to be explained how that took place? He said it was owing to the vermicular action of the urethra being towards the bladder instead of outwards. Mr Stapleton's explanation was that when the cat-gut got behind the stricture it swelled. He could understand how its swelling there might render it difficult to withdraw the instrument, but how it would draw it further on he was at a loss to know. However he was speaking of gum-elastic catheters, manufactured by Weiss, which did not swell, and which he had seen come out unaltered after lying in the bladder for twelve hours. It was his habit to dock his patients, and he asserted that when he removed the gum-elastic catheter it was as smooth and clean as when it was introduced; therefore, it could not be the swelling behind the stricture that brought the instrument into the bladder. As to Mr. Morgan's observations, which had afforded such pleasure to his friend, Mr. Wharton, he did not think they threw much light on the subject. They knew it was the action of the accelerator-urinæ muscle which forced out fluids injected into the urethra. Was it reasonable to say that this muscle would act in another way when a catheter was introduced—that it was so great an epicure that when it got hold of a nice gum-elastic catheter it drew it in further, but immediately rejected the nasty nitrate of silver?

THE PATHOLOGICAL SOCIETY OF IRELAND.

At the meeting of the Pathological Society on Saturday, Dr. **Kidd**, President, in the Chair,

Dr. **Bigger** brought under the notice of the Society a peculiar case of fracture of the neck of the thigh bones, which was a trite subject, and one about which at the same time many different opinions had been expressed. The subject of the case to whom he desired to call their attention was a person who formerly had been in good circumstances in life, but had been induced, owing to a fall in his position, to enter one of the valuable charitable institutions in this city. Previous to that period, some eight months, he had fallen, whilst in the act of passing out of his house—some children ran against him, and he fell on his hip, rose and proceeded a few paces, and fell a second time. He was then carried into the house, and a relative, a Medical gentleman, attended to him for some time, but he did not determine the question as to whether there was fracture or not. At length it was decided that the patient was suffering from a severe contusion of the joints, a common occurrence, and productive of very great difficulty of diagnosis. He was taken to hospital, but it was then thought that the man was not seriously injured, as he was able to walk with comparative ease. At length he was confined to bed with an attack of bronchitis, to which he succumbed after some days. On inspecting the trochanter, it was plain that the whole side of the hip was much flattened, and also a fulness existed anteriorly. There was a shortening of about one inch in the whole limb. All this Dr. Bigger perceived long before the man's death, but he did not know there was such considerable deformity as was afterwards found to be the case. On examination the capsule was found to be perfectly intact. In trying to get in a small saw to cut the bone across, he found himself opposed by some foreign body which proved to be a considerable exostosis, which appeared to be among the tendons and immediately below the minor trochanter. It was fully an inch long. The bone appeared sound, and the tissue was exceedingly firm—almost like ivory. On removing another part of it, he found that a false joint had been already formed, so curiously did those parts play upon one another. It was fifteen months since the fracture occurred, and he did not know that it was ever much displaced. When the man lay in bed he turned his foot very slightly outwards, and suffered great pain on the slightest abduction of the limb.

Dr. **Hayden** said he wished to bring under the notice of the Society a matter of some interest. On the 26th November last a man of small stature was sent over from Wales to be admitted under his (Dr. Hayden's) care. He was much emaciated; his age was 43, and the only history he (Dr. Hayden) could obtain of his illness was that he had been complaining of a severe pain in his abdomen, accompanied with irregularity of the bowels, for six months previously. On the right side of the abdomen a hard and rugged tumour, moveable, and manifestly composed of a number of distinct solid bodies, was detected. It yielded the characteristic percussion note of a solid body in front of the inflated intestines. The bowels were remarkably irregular. The pain of the abdomen, which was remittent, was always aggravated coincidently with constipation of the bowels. The fæces were of a singular character, resembling liquid mortar, and free from fæcal odour. The pulse were small and quick but regular, the action of the heart being exceedingly weak, the sounds feeble but distinct. The diagnosis made was scirrhus of the mesentery in the neighbourhood engaging that portion adjacent to the cæcum. Three or four days before the man's death—which occurred on December 31st, the pain in the abdomen became continuous and excessively severe. It was now impossible to feel the tumour, which, up to this time, had been distinctly perceptible, owing to excessive tenderness and inflation of the abdomen. Peritonitis had set in, and the man died on the 31st December. At the autopsy, it was discovered that perforation of the intestines consecutive to sloughing had occurred near the termination of the ilium. The scirrhus tumour had become quite pliable, easily broken up and detached, and this portion which had become discoloured by the effused fæces presented the appearance of intestinal scibold, and led him (Dr. Hayden) for a moment to doubt the accuracy of his diagnosis. It was a good example of a scirrhus mass. The portion which he presented for their inspection was attached to the intestines, and clearly showed the characters. There was, of course, peritonitis. There was a small scirrhus nodule in the cystic duct obstructing the passage. The gall bladder was distended with bile, but in no other situation was there cancerous deposit. The heart presented a good example of atrophy, of that form which was met with in almost every case of extensive cancerous disease, and due to the attendant cachexia. The pericardium was firmly attached to the heart, and was corrugated, clearly showing that there had been pericarditis, incident to atrophy of the heart. In the adventitious structure connecting the pericardium to the heart a number of osseous laminæ were formed near the base, and also to cartilaginous plates so called. These latter, examined microscopically, were found to be composed of nucleated fibrous tissue resembling cartilage corpuscles, but in one situation calcareous spicula were disposed in the form of *chevaux-de-frise*. The heart weighed only six ounces. The muscular substance was of a dark-brown colour, and in the granular stage of fatty degeneration. The cavities and valves were normal, as were likewise the great vessels of the coronary arteries connected with the heart, except that they were reduced in calibre proportionately to the size of the heart. The case, therefore, presented a good example of scirrhus of the mesentery, inducing general marasmus, including atrophy of the heart, and proving fatal by sloughing of the intestine and effusion of the contents into the cavity of the peritoneum. It was also interesting in reference to the existence of osseous and so-called cartilaginous plates in connection with pericardial adhesion. The only explanation Dr. Hayden could offer of the absence of colouring matter in the fæces had reference to obstruction of the cystic duct already mentioned.

Dr. **Law** said the subject of the case to which he wished to draw their attention was a coal porter, 50 years of age, who reported himself as enjoying good health until six weeks previous to his admission into hospital. He then got cold, and when suffering from the effects he attended a wake, where he became intoxicated. He walked home while it rained, and remained in his wet clothes during the night. His case afterwards became very severe, and each day he became worse, until his health failed completely, and he was at the end of six weeks compelled to seek admission into the hospital. His breathing was very much oppressed, and examination proved there was extensive disease in the direction of the anterior and posterior portions of the left lung, and also in the posterior portion of the right. Gangrene of the lung was suspected, and the man survived his admission only three days. The left lung was in a broken-down and disorganised condition. It could hardly be said to be gangrene of the lung, for the offensive smell which it emitted was not a characteristic essentially of that disease. It was more properly putrefaction. Dr. Law said he had seen a good number of cases, and had noticed them to occur under almost the same circumstances—all had resulted from the person becoming affected with cold while in a state of intoxication. In the apex of the lung they always had that broken-down condition. The trachea had an intensely red appearance. The right lung was less affected, but was still in a condition of remarkable disorder. In all these cases where persons had been seized while in a state of intoxication there was a discharge of blood. He believed that the unhealthy condition of the organ usually occurred in cases of inflammation of the lungs in which the ordinary precautions had been neglected. He had a large experience of these cases, and had always found this to be the condition. He had been recently sent for to see a person who was suddenly seized with hemorrhage, and on his arrival he found that the hæmorrhage was of an alarming degree. The man had been playing in a cricket match, and drank rather largely of champagne. He threw himself on the damp grass and shortly afterwards got ill. Subsequently he became much worse, and was treated for acute inflammation. He (Dr. Law) suggested tonic treatment, and rapid and marked improvement resulted. It was an important point to trace the disease and know how to treat it. Profuse expectoration of a green character was a most fatal symptom. He could point to many living persons who had suffered from the disease, but they were carefully watched and the exact point at which the tonic treatment could be adopted with advantage was observed and they had recovered.

Dr. Yeo showed the viscera of a female, æt. 52, who had suffered from albuminuria, great dyspnœa, and the signs of pleural effusion on the right side; weak, rapid, fluttering action of the heart, but no abnormal bruit. *Post-mortem* examination showed all the cavities of the heart dilated and distended with coagula. In the auricular appendices and at the apices of each ventricle, the structure of the clots was characteristic of *ante-mortem* formation, viz., dry, laminated, inelastic, brittle, of a dull yellowish-brown colour, and adherent; loosely attached to these were ordinary *post-mortem* coagulations which occupied the greater part of each cavity. The valves were all healthy. In the lower lobes of each lung, was a hard, airless, hæmorrhagic swelling, the arteries leading to which were tightly plugged with dry adherent clots, the infarctions on the right side occupied nearly the entire of the lower lobe, which was covered by fresh fibrinous exudation, and compressed by about two quarts of fluid. Innumerable small fibrinous infarctions occupied the cortical substance of the left kidney. Dr. Yeo thought it probable that the insufficient excretion of the urinary products had aided the coagulation of the blood in the weak dilated heart.

Dr. Bennett brought under the notice of the Society, a curious specimen of much interest, in a case of fracture of the neck of thigh-bone, which he met with in the course of dissection. The specimen showed that the joint was extremely laminated. It rotated inwards. The question which arose in his mind, was whether to regard it as a case of fracture or of morbus coxarius, and possibly the deformity might have originated in that, although the limb did not present the usual features of that disease.

The Society adjourned until Saturday the 25th inst.

St. Andrew's University.—It has been definitely arranged that Lord Neaves is to be formally installed as Rector of this University on Thursday, the 13th day of February, when he will deliver his Inaugural Address. We understand that Lord Neaves has signified his intention of offering four prizes annually during his term of office to be competed for by the students attending the University, in place of one large prize annually, as was the custom of previous Rectors.

Registered for Transmission Abroad.

THE
MEDICAL PRESS AND CIRCULAR
s published simultaneously in London, Dublin, and Edinburgh, every Wednesday morning. Price 5d. Post free, 5½d.

Post Free to Annual Subscribers	£1 2 6
„ If Paid in Advance	1 0 0

*** Post-office Orders and Cheques to be drawn in favour of—
A. A. Tindall, 20, King William Street, Strand, London, W.C.
A. H. Jacob, 23 Ely Place, Dublin.
Maclachlan and Stewart, South Bridge, Edinburgh.

Subscriptions for France are received by Messrs. Bailliere, Publishers to the Academie de Médicine, Paris—post free in advance, £1 6s. per annum.

Subscriptions for the United States are received in New York, by Messrs. Willmer and Rogers; Baltimore, by Messrs Kelly and Piet; Philadelphia, by Messrs. Lippincott and Co., and Dr. Butler, post free in advance, £1 6s., about six and a-half dollars; or direct from the Offices in this country for the same amount, by the new Post-office Order system.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 22, 1873.

THE LAST ILLNESS OF NAPOLEON III.

The public as well as the Professional journals have been crowded with details respecting the late Emperor which might as well have been left unrelated. The general result is that the public feels less confidence than ever in Medical skill, and a number of points of interest to the Profession have become inextricably mixed up with a tolerably simple case. The report of the *post-mortem* examination which we published last week has provoked much comment, and the dissent and opinion expressed by Sir W. Gull are generally pronounced uncalled for.

In our correspondence columns, which are always open to those with whom we differ as freely as to those with whom we agree, will be found expressions of individual opinions quite as valuable in reference to the points raised as that of Sir W. Gull, although to the latter, as the physician in actual attendance, undoubtedly must be attached the greatest value in reference to the *clinical* facts which he was called upon to interpret.

In this respect we cannot pass over the phrase that has been somewhat loosely employed about the inability to detect the extent of disease of the kidneys. It has been understood by the public, and the idea has been widely spread by the newspapers, that the report affirmed the impossibility of detecting disease of the kidneys, and we must confess that this interpretation might have been foreseen by those who agreed to the report. Sir W. Gull would have done more service to the Profession by pointing this out than by making an addendum of his own which could serve no useful purpose and which has caused much adverse comment.

Either he should have stayed to join in the consultation of his colleagues in the matter or appended his signature in the ordinary way. If he felt disinclined to that he might have omitted to sign it altogether in the assurance that his brethren would have regarded the presence or absence of his name with indifference. They looked to Dr. Burdon-Sanderson as the pathologist, and the addition of other names was a mere formality.

It will be remembered that we have published statements respecting the duration of the late Emperor's malady. On the same day as our last issue there appeared in Paris further details confirming our revelations. Dr. J. Lapeyrère records in the *France Médicale* some interesting details that demonstrate the truth of what we put forward, and which we therefore republish. He tells us on the authority of Dr. Guillon, that in 1866, during the stay of the Emperor at Vichy, the last named surgeon found a stricture of the membranous portion of the urethra at the point nearest the spongy part. A small bougie olivaire was employed by M. Guillon, and on the third day the Emperor was able to return to Paris—catheterism having been employed as a matter of precaution just before starting on the journey. Some days later, at Biarritz, the Emperor suffered from inflammation of the prostate gland, which was also treated by Dr. Guillon.

In commenting further on the published statements, Dr. Lapeyrère points out that the discussion that has been initiated by the official report would be far more appropriate in one of our Medical societies, where the doubtful or obscure points would assuredly be cleared up. We certainly think this would be far better than a recourse to the newspapers, and admit that only Professional journals should be made the media for such statements as have lately appeared in the lay press.

The article we have mentioned closes with enquiries as to the general condition of the patient and the effect of chloroform upon him. It then asks whether opium had any part in the sudden crisis—a question in which Sir W. Gull's opinion would be more valued than on the formation of calculus. Finally, it alludes to lithotomy in similar terms to those we employed last week. Whether the questions thus raised receive due consideration or not, we do hope that for the future the leading principles of Medical ethics will be strictly observed even when eminent men are called in to relieve Emperors. From henceforth it will be no credit to a Medical man to issue for publication in the newspapers bulletins of the condition of their important patients.

Another aspect of the matter appears in some of Saturday's papers which state that the *American Register* has published a letter from Sir Henry Thompson, dated the 13th inst., to Dr. Evans, dentist to the late Emperor, explaining the causes of the Emperor's death. Sir Henry Thompson protests against the accounts respecting his mode of practice given by some French journals as wholly inaccurate, and demonstrates the necessity of his mode of treating the Emperor's case. Sir Henry says that the "Emperor did not die from any effect of mechanical treatment, but because the kidneys were in an advanced stage of disease. The pelvis and the ureters were both largely dilated, the left ureter being as large as the aorta. In such conditions I have long ago given it as my deliberate opinion that lithotomy offers no better chance than lithotrity. The instrument used was small. The longer I live the fewer, simpler, and smaller are my tools." Sir Henry Thompson refers to his lecture on lithotrity at the University College Hospital in November last as a complete answer to those who speak of his operation as rough or painful. He says, "I rarely use chloroform. Often no expression of pain is heard. The sitting never exceeds two minutes."

It is not our business to find out why the great dentist should have communicated such a private note to the papers, but we may say that its publication only shows the propriety of the comments we have made.

◆

HOSPITAL SUNDAY.

There seems now a good prospect that the great "Birmingham invention" for helping hospitals will be utilised in the metropolis, after which there can be little doubt it will rapidly spread.

True there are some difficulties to be overcome, but they are not insuperable. As to sectarianism interfering with such a work we should be ashamed to believe that it will be permitted so to do. In the cause of charity men have long learned to sink theological differences, and they have only therefore to carry out in one more detail a principle to which they have long done homage.

A great Birmingham divine—the late Rev. J. Angell James, once said in the Town Hall that there was "no sectarianism in misery, and should be none in mercy," and his words cannot be better applied than to the proposal to try in London a plan that has succeeded in the capital of the Midlands.

At a public meeting last week, over which the Lord Mayor presided, an influential council was elected to carry out the resolutions passed in favour of a Hospital Sunday, and we are not sure that the scheme will not go far towards superseding dinners, bazaars, and other methods of obtaining support which have no recommendation but that of the money they bring in.

It is, of course, absolutely essential to success to secure the hearty co-operation of the ministers of all sects, and so far, we have every reason to be satisfied, when we find the Roman Catholic Archbishop, the Chief Rabbi, and the leaders of the nonconformist bodies joining with the dignitaries of the Church of England in the good work. If we were to offer any criticism it would be in reference to the preponderating numbers of the clerical members of the Council. To have half clerics and half laymen leaves the Medical element smaller than it should be. We would have suggested a larger number of Medical men on the Council. One-third clerics, one-third Medical men, and one-third neither, would have given a more powerful Council.

◆

Notes on Current Topics.

Embolism of the Art. Central. Retinæ.

At the first meeting of the Imperial Gesellschaft der Arzte, of Vienna, a most valuable essay was read on this subject, which is one not only of interest as a pathological phenomenon, but its bearings and history are likewise highly important. Virchow made one of his most brilliant suggestions *apropos* of this subject, and the expectation which he expressed in his work "On Embolism," that embolism of the a. centr. retin. would one day be diagnosed by aid of the ophthalmoscope, was not long after realised by V. Graefe, whose diagnosis was shortly afterwards verified at the autopsy of the patient. Prof. Mauthner in his communication stated that embolism of the a. centr. retinæ occurs under similar circumstances to that found in the cerebral vessels, in cases of heart disease and atheromatous disease of the arteries, where small masses are carried forward by the current of the blood into the smaller arteries, the cavity of which they block up more or less completely. One of the most important questions relative to the a. centr. retin. is, whether it is a terminal artery communicating directly with the capillary vessels, or whether it has several terminal branches which would keep up a collateral circulation, and to a greater or less extent counterbalance the effect of the interruption caused by an embolus. Prof. Mauthner believes that it is not a terminal artery, because of its anastomoses with the ciliary arteries. However, as the anastomoses are not extensive and the circulation is not readily established, embolism of the a. centr. retin. is a serious occurrence, amaurosis resulting from it at an early stage. Examination during life shows the arteries atrophic and quite invisible towards the periphery, following sudden loss of sight. The veins are diminished in size towards the periphery. Cardiac disease and atheromatous degeneration of the arteries lend stronger support to the diagnosis. The lecturer differed from Mackenzie and Brown-Séquard as to the cause of sudden blindness of one eye, generally the left, in right hemiplegia. It is the result of embolism of the left a. centr. retin. occurring along with that of the cerebral arteries. The anatomical relations of the left carotid account for the greater frequency of embolism in the left eye; as the carotid on that side rises in a straight direction from the aorta, it does not offer the obstruction which may be found in the anonyma or right carotid.

A Medical Knight.

We are glad to see that a knighthood has been conferred on another member of the Profession, viz., Mr. J. Cordy Burrows, F.R.C.S., three times Mayor of Brighton. It reminds us, however, of the long-promised honours to the Profession that the Government still neglects to bestow.

Metropolitan Hospital Sunday.

At a conference last Thursday the following resolutions were adopted :—

1. "That the success attending Hospital Sunday collections in many of the largest provincial towns induces the belief that this movement will be equally successful in London; it is, therefore, most desirable that simultaneous annual collections should be made in all places of worship in the metropolis on behalf of the Medical charities." Proposed by Rev. Canon Miller, seconded by Rev. Dr. Kennedy, supported by Sir Anthony Rothschild.

2. "That a representative council be elected, by public meeting annually, consisting of not less than twenty-five clerical and twenty-five lay members, to make arrangements for the Hospital Sunday collection." Proposed by Right Rev. Bishop Claughton, seconded by Archbishop Manning.

3. "That the council have power to appoint an annual Committee of Distribution, consisting of members unconnected with hospitals, whose decision shall be final." Proposed by Rev. Dr. Jobson, seconded by Mr. R. B. Martin, supported by Dr. Sedgwick Saunders.

4. "That the Lord Mayor be permanent president and treasurer of the fund, and that the annual meetings be convened by him." Proposed by Mr. Robert Few, seconded by Rev. Prof. Marks.

5. "That the system of distribution be based upon the last three years' expenditure of each institution, after deducting the income derived from endowments, realised property, and legacies exceeding £100." Proposed by Rev. Dr. Davidson, seconded by Mr. Jabez Hogg.

6. "That no institution be admitted to participate in the distribution of the fund if the Committee of Distribution find the cost of its management exceed a reasonable percentage of the whole current expenditure." Proposed by Rev. J. F. Kitto, seconded by Rev. J. R. Bristow, supported by Rev. Canon Oakley.

Gratuitous Medical Advice.

At a meeting of general practitioners at the London Tavern on Thursday evening, to discuss the evils of gratuitous advice, Dr. Leslie in the chair, the abuses of hospitals were discussed with energy, and a committee formed to take action.

Anæsthetics in Midwifery.

As the use of anæsthetics is just now exciting so much attention, the following summary of an interesting paper upon their employment in obstetrical practice, by Dr. Dougan Clark, in the *American Journal of Medical Sciences*, will be found interesting :

"1. In perfectly normal labours of moderate suffering and duration, and without untoward symptoms of any kind, anæsthetics should not be resorted to.

"2. If the pains, even in an otherwise normal labour, be inordinate and protracted, especially in the second stage, anæsthetics are indicated.

"3. Irregular pains, exhaustive in their character, and inefficient, may be tranquillized by anæsthesia, and afterward the action of the uterus is, as a rule, more regular and efficient.

"4. Threatened convulsions may be averted, and those existing may be terminated, by a judicious use of anæsthetics. In cases of eclampsia, however, with congestion of the brain, or organic disease of that organ from any source, they are contra-indicated.

"5. Anæsthesia is proper in all obstetrical operations, whether manual or instrumental. It is useful in eversion, embryotomy, and the use of the forceps, and indispensable in Cæsarean section.

"6. Anæsthetics are among the most reliable means of overcoming rigidity of the perineum, os uteri, or vagina, especially when depending upon muscular excitement.

"7. Chloroform or ether may be employed for anæsthesia, of which chlorofom is the most convenient, agreable and efficient, but ether in midwifery, as in surgery, is the most safe.

"8. Chloroform is much less dangerous in midwifery than in surgery, so far as past experience can determine.

"9. It is not necessary, as a rule, to bring about complete insensibility, but only sufficient to obtund the severity of the pains. The exceptions to this rule will readily suggest themselves to a thinking mind."

Poison in the Ball-room.

We read last week in one of the newspapers a sensation paragraph to the effect that a lady had to be conveyed out of the room at the last *bal masque* in Paris in a complete state of prostration, which turned out to have been caused by the poisonous particles emanating from a green robe she wore. Powerful antidotes had to be employed to recover her. Now, dangerous as the greens produced by arsenic are, they do not manifest their presence by causing a fainting fit at the outset, and there are other conditions in most ball-rooms which do, so that the occurrence is easily explicable.

Dr. Brewer.

We regret to say that the hon. member for Colchester, whose illness in Italy we announced and afterwards his convalescence, has had a relapse. He has, however, happily recovered from this, and was able last week to commence his homeward journey by slow stages. The Italian physicians, considering the nature of the case, felt it was desirable for their patient to move northwards as early as possible.

Lithotrity and History.

The *Bordeaux Médical* asserts that Sir H. Thompson did not perform the operation on the late King of the Belgians, but that the crushing was actually done by M. Civiale, the father of lithotrity. When shall we ever know what actually transpires, and how true history is?

London International Exhibition, 1873.

At a meeting of Surgical Instrument Manufacturers held on Friday, it has been resolved:—

1. That the surgical instrument manufacturers do not exhibit unless the conditions requiring their productions to be submitted to a committee of selection be withdrawn.
2. That they may exhibit all the articles of their manufacture as a whole, and not in sections or subdivisions as proposed by the Commissioners.
3. That the condition on which the foreigner and Englishman exhibit shall be one and the same.

Two New English Words.

A correspondent of the *Medical Archives* thinks it desirable that professional prostitution should be designated in such manner as would distinctly and definitely indicate what vice or evil was alluded to, and proposes two substitutes for social evil and Lock Hospitals. To this end, in analogy with pornography and psychiatria (see Webster and Worcester's Dictionaries, new edition), he suggests two new English words, one of which was used by the ancient Greeks, while the other, although not used, would have readily been understood by them. Thus, as from the Greek λυκειον we have lyceum, so from the Greek πορνειον—brothel—we may say porneum; and, instead of the lengthy and really meaningless expression "social evil hospital," he proposes the short and expressive one, "porniatria" or "porniatric" house, or home, or, "porniatric hospital," from the Greek πορνε, prostitute, and ιατροσ, physician or healer.

How not to do it.

The West Ward Union, so clever at setting at nought the Local Government Board, has now resolved that it is not desirable to join with the other two wards in the appointment of a Medical officer under the Sanitary Act.

The Use of Ergot by Midwives.

The French Academy of Sciences has been recently exercised with the discussion of a question which was referred to them by the Government and which, it would seem, they had some difficulty in settling.

The French law, while it provides for the examination and qualification of midwives, forbids them using ergot in their practice, and French apothecaries, therefore, refuse to supply it on their order. The Academy appears to have felt that serious doubts might exist as to the propriety of allowing the use—and, perhaps, the abuse—of the drug to such persons but, that as the law recognised them as legitimate practitioners it would stultify itself if it refused them the necessary means to practise their business.

By the will of Mr. W. J. Horn, of Sheffield, the General Infirmary of that town receives a legacy of £2,000, and the Public Dispensary, £1,000.

An examination of candidates for appointment as Assistant-Surgeons in Her Majesty's Indian Medical Service will be held at Burlington House, on Feb. 17th.

The old national Pharmacopœia and system of weights and measures is to be abandoned in Bavaria, in favour of a Pharmacopœia Germanica and the decimal system of measurement.

Notice is given that a competitive examination of candidates for admision into the Medical Service of the Royal Navy will take place at the University of London, Burlington Gardens, on Monday, Feb. 17th, and following days, at ten o'clock.

In view of the growing importance of Medical galvanism, the Academy of Sciences of Bologna has announced its intention to present a prize of 1,200 francs for the best scientific experimental essay on galvanic or dynamic electricity. The competition remains open until June 30, 1874.

Dr. Robert Smith, Professor of Surgery in the University of Dublin, and Surgeon to the Richmond Hospital, has announced himself as a candidate for the Vice-Presidency of the Irish College of Surgeons, which will probably become vacant next June by the elevation of the present Vice-Chairman, Dr. Denham, to the Presidency.

The offices of Assistant-Surgeon and Physician for the Treatment of Diseases of the Skin in the Charing-cross Hospital are vacant. The Assistant-Surgeons are required to be Fellows of the Royal College of Surgeons of England.

The Assistant-Surgeons and the Physicians for the treatment of Diseases of the Skin are required to reside within three miles of the Hospital.

We have reason to believe that Dr. Sawyer, Professor of Midwifery in the Irish College of Surgeons is, in consequence of his impaired health, anxious for a temporary retirement from his professorial duties, and that a request from him for the appointment of a *locum tenens* to deliver the winter course of lectures will be shortly laid before the Council of the College.

Prof. L. Popoff has published in the Berlin *Klinisch Wochenschrift*, No. 33, 1872, the results of a series of experiments carried out in the laboratory of Prof. Botkin, of St. Petersburg, on the infectiousness of cholera excretions. The conclusions arrived at were that, not only the intestinal dejections, but also the urine of cholera patients are infectious when introduced into the body; that cholera excretions are more distinctly infective when fresh than when old; when decomposition has commenced, the specific cholera-effects are masked by the effects of the decomposing matter; from one to three (or even more) days are required for the production of the effects of cholera-poison introduced into the bodies of animals; lastly, the poison can affect the system by direct injection into the blood without passing through the intestinal tract.

Active steps have been taken in Munich to meet the probable outbreak of cholera. It has been determined at once to erect the necessary hospitals, and appoint Medical officers for the various districts. The chief physician to a hospital will receive 6, the junior 4 florins daily (about 10s. and 6s. 8s. respectively). The police has issued a circular to the owners of hotels, coffee-houses, and such like places, warning them of the danger of importation, and giving suitable advice. The immediate emptying and daily disinfection of ashpits, privies, &c., is urged. As disinfectants, the following are recommended:—1. Chloride of iron and manganese, 3s., 4s. per lb.; 2. Sulphate of iron; 3. Fluid carbolic acid of commerce, 4d. per lb.—(*Aerzl. Intell. Blatt.*)

An instructive instance of the impracticability of the law was brought under public notice at the Westminster Police Court the other day. A man came forward and complained to the magistrate that he found a chemist, stupidly drunk, compounding medicines in his own shop, and that, though he objected to have his physic dispensed by such a person, others had unwittingly done so, and one woman complained that a powder which the chemist had made up had nearly killed her child.

The magistrate's reply was a curious abstraction of Mr. Bright's famous adulteration epigram, *caveat emptor*. He informed the complainant that the chemist might drink if he liked in his own shop, and the best remedy he suggested was not to deal with such a man "if he sold drugs to persons which injured them he could be made amenable to the law."

We suppose that the moral of this decision is that you should take no medicines until you know that it was made up by a sober man, and if it poisons you you may go to law, but until it does you have no right to complain.

Dr. Schaffer contributes to the *Aerzl. Intell. Blatt.* an interesting case of epilepsy due to laceration of the N. sciaticus. The patient enjoyed perfect health until he was shot in his left thigh near Orleans, Nov. 7, 1870. Unsuccessful attempts were made to extract the bullet. The foot became swollen and useless. In February he had an attack of "cramp" of short duration, but succeeding these severe epileptic convulsions of a very violent type, the attacks lasting several hours. They commenced at a painful spot in the cicatrix, ran up the left nates and spine to the back of the head, and ended with convulsions. At the earnest entreaty of the patient, Dr. Schäffer cut down on the painful place where the patient insisted the bullet lay, and carefully dissected between the mem. biceps and semitendin. The mem. semi-membran. and adduct. magn. were also examined, but unsuccessfully. The wound was closed with suture. Severe fever followed, and a counter-abscess formed on the other side of the thigh. Patient rallied, however, and had no return of the fits.

STUDENTS' COLUMN.

SYNOPTICAL REVIEW OF THE OFFICINAL PREPARATIONS OF THE BRITISH PHARMACOPŒIA.

By W. Handsel Griffiths, Ph.D., L.R.C.P.E.,
Assistant-Librarian Royal College of Surgeons in Ireland.

VAPORES (INHALATIONS).

There are five of these preparations now officinal. They should be so administered in a suitable apparatus as to enable the patient to breathe without effort the volatile ingredients evolved. They are as follows:—

Vapor Acidi Hydrocyanici.—10 to 15 mins. of acid to 1 drm. of *cold* water.

Vapor Chlori.—2 ozs. of chlorinated lime, and a sufficiency of water to moisten.

Vapor Coniæ.—60 grs. of extract of hemlock, 1 drm. of solution of potash, and 10 drms. of distilled water. 20 mins. of the mixture are to be put on a sponge, and the vapour of hot water passing over it to be inhaled.

Vapor Creasoti.—12 mins. of creasote and 8 ozs. of *boiling* water. Cause air to be passed through the mixture, and inhale it.

Vapor Iodi.—1 drm. of tincture of iodine and 1 oz. of water. Apply a gentle heat and inhale the vapour.

The addition of the alkali in *Vapor Coniæ* at once develops the characteristic odour of the hemlock.

VINA (WINES).

Wine, in consequence of the alcohol contained, and in some instances owing to the acidity, is a solvent of many substances insoluble in water. Wines, however, are sometimes objectionable, both from their liability to undergo decomposition, and owing to the fact that the proportion of alcohol present is by no means always constant.

Including Vinum Aurantii and Vinum Xericum there are eleven medicinal wines in the present Pharmacopœia, viz.:—

Vinum Aurantii, Orange Wine.
" **Xericum**, Sherry.
" **Ferri**.
" **Colchici**, 1 in 5.
" **Rhei**, 1 in 15½, or 38 grs. to 1 oz.
" **Ipecacuanhæ**, 1 in 20, or 22 grs. to 1 oz.
" **Opii** (*Extract*), 1 in 20.
" **Aloes**, 1 in 26½.
" **Ferri Citratis**, 1 in 60, or 8 grs. to 1 oz.
" **Antimoniale**, 1 in 240, or 2 grs. to 1 oz.
" **Quiniæ**, 1 in 480, or 1 gr. to 1 oz.

Orange wine forms the basis of Vinum Ferri Citratis and Vinum Quiniæ; sherry, that of all the other wines.

The following are the ingredients of the wines:—

Vinum Aloes.

Socotrine Aloes	1½ ozs.
Cardamon Seeds	80 grs.
Ginger, *coarsely powdered*	80 grs.
Sherry	2 pints.

Vinum Antimoniale.

Tartarated Antimony	40 grs.
Sherry	1 pint.

Vinum Colchici.

Colchicum corm., *sliced, dried, and bruised*	4 ozs.
Sherry	1 pint.

Vinum Ferri.

Fine Iron Wire	1 oz.
Sherry	1 pint.

Vinum Ferri Citratis.

Citrate of Iron and Ammonia	160 grs.
Orange Wine	1 pint.

Vinum Ipecacuanhæ.

Ipecacuanha, *bruised*	1 oz.
Sherry	1 pint.

Vinum Opii.

Extract of Opium	1 oz.
Cinnamon Bark, *bruised*	75 grs.
Cloves, *bruised*	75 grs.
Sherry	1 pint.

Vinum Quiniæ.

Sulphate of Quinia	20 grs.
Citric Acid	30 grs.
Orange Wine	1 pint.

Vinum Rhei.

Rhubarb Root, *coarse powder*	1½ ozs.
Canella Alba Bark, *coarse powder*	60 grs.
Sherry	1 pint.

It will be seen on reference to the above that all the wines may be said to be simple, except *Vinum Aloes*, *Vinum Opii*, and *Vinum Rhei.*

All the wines are made by maceration (pressing and straining when necessary) and subsequent filtration, except *Vinum Antimoniale*, *Vinum Ferri Citratis*, and *Vinum Quiniæ*, and these are made by simple solution, and subsequent filtration.

Vinum Xericum contains from 17 to 18 per cent. of alcohol, with colouring matter, œnanthic ether, &c., and bitartrate of potash, malates and sugar, &c.

Vinum Aurantii is made by fermenting a saccharine solution to which the fresh peel of bitter orange has been added. It contains about 12 per cent. of alcohol, and is slightly acid.

In *Vinum Antimoniale*, when the tartarated antimony is impure or the wine of inferior quality, perfect solution is often impossible, and the salt is frequently decomposed; the wine often contains matters which cause precipitation of the *oxide* of antimony.

Vinum Ferri very probably contains *tartrate of potash and iron*, formed by the action on the iron of the bitartrate of potash contained in the sherry.

Vinum Ipecacuanhæ when long kept not unfrequently throws down a precipitate of a mixture of bitartrate of potash and cephaelate of emetina.

Vinum Quiniæ is a solution of neutral sulphate and citrate of quinine in orange wine; the citric acid aids materially in the solution of the disulphate.

UNCLASSED PREPARATIONS.

Adeps Præparatus.—The fat of the hog (sus scrofa), purified by removing the membranes, washing thoroughly in a stream of water and straining, then liquifying at a heat not exceeding 212° F. and again straining.

It is soft, and melts at about 100°. It should not have a rancid odour, and should dissolve entirely in ether. It consists of about 60 per cent. of olein, with some palmitine and stearine. Distilled water in which it has been boiled should not give a precipitate with nitrate of silver, (absence of chloride of sodium), and should not give a blue colour with solution of iodine, (absence of starch).

It enters into the composition of *Adeps Benzoatus*, and forms the basis of many ointments.

Adeps Benzoatus.—Made by heating in a water bath for two hours, 1 lb. of prepared lard, and 160 grs. of coarsely powdered benzoin, and finally straining.

Benzoin, as we have elsewhere stated, has the property of preventing lard from becoming rancid.

Adeps benzoatus enters into the composition of all the suppositories, and forms the basis of the following ointments:—

Unguentum Gallæ, *Unguentum Plumbi Acetatis*, *Unguentum Sulphuris*, and *Unguentum Zinci.*

Sevum Præparatum.—The internal fat of the abdomen of the sheep, (ovis aries), purified by melting and straining. It is smooth, nearly scentless, and fusible at 103°. It consists chiefly of oleine and stearine. It enters into the preparation of *Emplastrum Cantharides*, and *Unguentum Hydrargyri.*

Sapo Durus.—Hard soap formed by combination of olive oil and *soda.* It is composed of oleate and palmitate of soda. It is greyish white, horny, easily powdered when kept in dry air, and easily moulded when heated. The presence of a little oxide of iron gives it a red or blue marbled appearance. It is soluble in water, and the solution is precipitated by lime, lead, &c. The ash left after incineration does not deliquesce; it should be entirely soluble in rectified spirit, and should not give an oily stain to paper. It enters into the composition of *Emplastrum Resinæ*, and *Emplastrum Saponis*, *Extractum Colocynthidis Compositum*, *Linimentum Potassii Iodidi cum Sapone*, *Pilula Aloes Barbadensis*, *Aloes et Assafœtida*, *Aloes Socotrinæ*, *Cambogiæ Composita*, *Rhei Composita*, *Saponis Composita*, and *Scillæ Composita.*

Sapo Mollis.—"Soft soap" formed by combination of olive oil and potash. It is composed of oleate and palmitate of potash. It is yellowish-green, transparent, and gelatinous.

The ash left after incineration is very deliquescent; like hard soap it should be entirely soluble in rectified spirit, and should not impart an oily stain to paper. It enters into the composition of *Linimentum Terebinthinæ.*

Pyroxylin.—"Gun cotton," prepared by immersing 1 oz. of cotton in a mixture of 5 ozs. each of sulphuric and nitric acids, for three minutes, then washing out the acids well with water, until the washings cease to give a precipitate with chloride of barium, and finally draining on filtering paper, and drying in a water bath.

It is readily soluble in a mixture of ether and rectified spirit. When exploded by heat it leaves no residue. It is introduced into the Pharmacopœia for the preparation of collodion.

Collodium.—Collodion is a solution of 1 oz. of pyroxylin in a mixture of 36 ozs. of ether, and 12 ozs. of rectified spirit.

This is a colourless liquid with an etherial odour; it is highly inflammable, dies rapidly on exposure to the air, forming a transparent film which is insoluble in water or rectified spirit.

Collodium Flexile.—Is a mixture of 6 ozs. of collodion; 120 grains of Canada balsam; and 1 drm. of castor oil.

Æther.—"Sulphuric ether of Edin. and Dub." Contains not less than 92 per cent. by volume of pure ether, $(C_4H_{10}O)$.

It is unnecessary to give in detail the complicated process for preparing ether, as given in the Pharmacopœia. Suffice it to say, in general terms, that it is prepared by the action of 10 ozs. of sulphuric acid on 50 ozs. of rectified spirit, added in successive portions. It is purified by allowing it to stand on chloride of calcium and slaked lime, and re-distilling to the sp. gr. of 0·735.

The following is a brief explanation of the process:—

By the reaction of sulphuric acid on rectified spirit, *sulphovinic acid* $(C_2H_6SO_4)$ is first formed, thus:—

$$H_2SO_4 + C_2H_6O = C_2H_6SO_4 + H_2O$$

By the reaction now of alcohol on the sulphovinic acid, the latter is decomposed, forming sulphuric acid and ether, thus:—

$$C_2H_6SO_4 + C_2H_6O = H_2SO_4 + C_4H_{10}O$$

By the addition of more alcohol, sulphovinic acid is again formed, and thus by the continuous supply of alcohol, the production of ether becomes continuous, sulphovinic acid being an intermediate product.

It is a colourless, volatile, inflammable liquid, with a characteristic odour; boils below 105°. Fifty measures agitated with an equal volume of water are reduced to 45 by an absorption of 10 per cent. It leaves no residue on evaporation.

It enters into the preparation of *Æther Purus*, *Collodium*, *Collodium Flexile*, *Liquor Epispasticus*, and *Spiritus Ætheris.*

Æther Purus.—Ether free from either alcohol or water. The process of purification is effected by washing the ether well with water (by which the spirit is removed), and when the liquids have separated after a couple of minutes, decant the supernatant ether; digest the latter then for 24 hours, with recently burned lime and chloride of calcium (to remove the water), and finally distil with the aid of a gentle heat. Its sp. gr. should not exceed 0·720, and it should not coagulate the albumen of the blood; if alcohol be present, the sp. gr. will be exceeded, and it *will* coagulate the albumen of the blood.

Water and sulphurous acids are occasional impurities, the former increasing its specific gravity, the latter imparting to it an acid reaction.

Chloroformum.—Terchloride of Formyl ($CHCl_3$).

The following is an abstract of the Pharmacopœial method of preparing chloroform:—3 galls. of water and 30 ozs. of rectified spirit are distilled with a mixture of 10 lbs. of chlorinated lime and 5 lbs. of slaked lime; 50 ozs. of the distillate is well washed with water, and after the mixture separates into two strata, the lower one, which is crude chloroform, is removed, washed repeatedly with successive portions of distilled water, and then shaken with its own volume of sulphuric acid. When the mixture settles, the chloroform is again separated, mixed with 2 ozs. of chloride of calcium, and ½ oz. of slaked lime and again distilled.

The following reactions indicate the probable steps in the process.—

1st. $\underbrace{2C_2H_6O}_{\text{Alcohol.}} + \underbrace{O_2}_{\text{Oxygen.}} = \underbrace{2C_2H_4O}_{\text{Aldehyd.}} + \underbrace{2H_2O}_{\text{Water.}}$

2nd. $\underbrace{C_2H_4O}_{\text{Aldehyd.}} + \underbrace{3Cl_2}_{\text{Chlorine.}} = \underbrace{C_2HCl_3O}_{\text{Chloral.}} + \underbrace{3HCl}_{\text{Hydrochloric Acid.}}$

3rd. $\underbrace{2C_2HCl_3O}_{\text{Chloral.}} + \underbrace{Ca2HO}_{\text{Hydrate of Calcium.}} = \underbrace{Ca2CHO_2}_{\text{Formate of Calcium.}} + \underbrace{2CHCl_3}_{\text{Chloroform.}}$

The process as a whole may be thus expressed:

$$\underbrace{4C_2H_6O}_{\text{Alcohol.}} + \underbrace{8CaCl_2O_2}_{\text{Hypochlorite of Calcium.}} =$$

$$\underbrace{2CHCl_3}_{\text{Chloroform.}} + 3(\underbrace{Ca2CHO_2}_{\text{Formate of Calcium.}}) + \underbrace{5CaCl_2}_{\text{Chloride of Calcium.}} + \underbrace{8H_2O}_{\text{Water.}}$$

Chloroform is a colourless liquid with a peculiar ethereal odour and sweet taste. Its sp. gr. is 1·49. It is slightly soluble in water, but soluble in all proportions of alcohol and ether. It is neutral in reaction, should not be coloured by sulphuric acid, and should leave no residue or unpleasant odour after evaporation. It is decomposed by fixed alkalies, and, on exposure to air and light, is apt to be decomposed into hydrochloric acid and chlorine. It is a powerful solvent of caoutchouc, gutta-percha, resins, many fats and vegetable alkaloids.

The following are its Pharmacopœial preparations:—*Linimentum Chloroformi*, *Spiritus Chloroformi*, and *Tinctura Chloroformi Composita*.

Charta Epispastica.—"Blistering Paper." Prepared by digesting 4 ozs. of white wax, 1½ oz. of spermaceti, 2 ozs. of olive oil, ¾ oz. of resin, 1 oz. of cantharides, and 6 ozs. of distilled water, in a water bath for two hours, stirring them constantly and then straining. Mix ¼ oz. of Canada balsam with the melted plaster, and pass strips of paper over the surface of the hot liquid.

Correspondence.

FOREIGN BODY IN THE BLADDER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Perhaps you may think the following case worth a place in your Journal:—

Mary G., æt. 14, was brought to my study on the morning of December 3rd, 1872, suffering, as the mother thought, from "a fit of the gravel." She had almost incessant desire to pass urine, acute pain in doing so, and pain on pressure over the bladder, quick pulse, nausea, and considerable fever. I looked upon the case as one of acute cystitis, and gave her in consequence, a mixture containing opium, belladonna, and camphorated barley water, ordering her a hip bath, and immediately after a light linseed poultice to be applied over the bladder. I saw her the following morning, and found her considerably easier, having slept pretty well the night before, but from information I received in the meantime from the mother, I introduced very cautiously a No. 10 silver catheter, and before it reached the bladder, I distinctly felt it coming in contact with some foreign body. I withdrew the catheter, and introduced a small polypus forceps, and without any trouble, the foreign body, which consisted of a common clay pipe, shank two and a quarter inches long, with the small tubercle at the lower part of the bowl, and two inches of a small iron chain attached—removed. Fortunately it was the chain that was caught, for if it had been the tubercle end of the shank, it is probable the chain might have slipped off and remained in the bladder.

She informed me afterwards, that four days previous to her consulting me, she had been introducing the smaller end of the shank into the meatus urinarius, and by some mishap "it slipped out of her fingers."

I need only add that by removing the cause she got rid of the effect. Yours truly,

P. M. Rice, L.R.C.S.I.

Millbrook House, Galway, January 9th, 1873.

MODIFIED HOMŒOPATHY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—You were good enough to include me in the list of qualified practitioners to whom you sent the number of your journal for December 18th last. I thank you for your courtesy. But that copy of the journal contains an article headed "Modified Homœopathy," which I do not hesitate to say is altogether untrue if it be intended to apply to homœopathic practitioners generally. When I say this I admit you were probably provoked to write the article by the one to which you allude in the *Homœopathic Review*.

I assume that your quotation from the *Review* is accurate, because I do not regularly see the *Review*, and therefore cannot tell if the extract has been rightly given. But I am willing to believe that, as a gentleman occupying a good professional position, you would not descend to the meanness of giving a wrong abridgement, in order to gain a temporary triumph for the cause you advocate.

If the editor of the *Homœopathic Review* has written anything to imply that it ever is necessary for a competent homœopathic practitioner to fall back on allopathic expedients for the treatment of disease, then I say I cannot allow that gentlemen to speak for me, for I never have occasion to do anything of the sort. During the more than seventeen years that I have practised homœopathy in this town I assert deliberately that I have never given, or found it necessary to give, even a single dose of aperient or purgative medicine, in any shape or form, in a general practice of average extent, embracing the varied forms of disease continually seen in such practice, namely, small-pox, typhus and typhoid fevers, croup, and other inflammatory affections of the air passages, the brain, eye, throat, and abdominal organs. A very large proportion of my patients recover, very few die, and those who do are the sufferers from disease that would be incurable under any known mode of treatment. This statement can be verified by reference to the lists of the registrars of deaths. Further, for seventeen years or more I have never bled or ordered a leech to be applied, nor cupped, nor used or ordered a blister, seton, issue, croton oil, or other counter-irritant, or salivated, or given laudanum, opium, morphine, or chlorodyne to abate pain, or used tartar emetic ointment, painted with iodine, or any of the like barbarities of allopathic practice, which you amusingly nickname "*scientific!* medicine!!" Yet my patients get well. What more do *I* want? What more do *they* require? But in my treatment of disease I select my remedies—specially prepared after my own formulæ—according to the logical, truly scientific mode, and natural law laid down for us by Hahnemann, from which I never deviate. The only other adjuncts I ever use are those of hydropathy. But as these cannot be extensively employed in private practice I only occasionally use them. Do not misunderstand me. I am not a magician, nor do I claim for the means I use any magical power. I only claim an earnest desire to see my patients get well without the infliction of medicinal disease, and reason and experience have proved to me that the means I use are abundantly sufficient to cure all that is curable of human malady. Again, I ask what more do I want?

But do I judge rightly of cause and effect? Either I am grossly deceived in diagnosing a case of inflammatory disease, or the disease does occur and the treatment cures it. If the treatment does cure it, then there is abundant curative power in properly selected homœopathic means. If, as you say, there is no curative action in the means made use of, then *Nature* cures. If Nature cures, she will cure for an allopath as well as for a homœopath. Medical men, then, will not be wanted, and there can be no other conclusion but that allopathy must be one of the greatest delusions that was ever inflicted on an ignorant, credulous public. Whichever horn of the dilemma you prefer I would have you take.

Sooner or later Government must interfere, and cause a ward in every London and provincial hospital to be set apart for the treatment of disease by homœopathy. It might be a fever ward, or lock ward if wished. Such a ward, under efficient direction, I think would enlighten the understanding of my allopathic barbarian brother—would induce him to throw his *pills*, *mixtures*, *lotions*, and *blisters*, to the "moles and to the bats"—and, having the "beam" removed from his eye, be astonished at his previous antagonism to *truth*.

I ask you in fairness to insert this letter in your journal. A copy will be sent to the editor of the *Homœopathic Review*, because if he has given the advice alleged, it could only be for inexperienced men, whose knowledge of homœopathy is distantly future. I am, Sir,

Your obedient servant,

Southsea, W. Hempson Denham, M.R.C.S.
January 2nd, 1873.

[We are glad to publish the communication of our correspondent because, if his practice coincides with the principles expressed in his letter, we have been lucky enough to hit upon the Medical dodo—the homœopath *pur et simple*. There is no doubt whatever that we have quoted the *Homœopathic Review* correctly. The pronouncement of that journal (which we must presume represents at least an important section of that profession) is as follows:—

"The obligations of the homœopathic practitioner to his patients to relieve pain and to stave off death are higher than his duty to practise homœopathy. If he cannot, whether from the incompleteness of science, or from his own imperfect acquaintance with it, prescribe homœopathically, he must use such measures as, within his knowledge, are most likely to achieve the end he has in view. He is the most successful physician who, within the limits where a homœopathically acting medicine can effect good, can relieve and cure, *most seldom* falls back upon an allopathic palliative."

The editor of the *Review*, in noticing our observations, says:—

"The only cases where anyone who understands homœopathy, or who is familiar with the *Materia Medica*, would care to resort to a sedative or an aperient, are cases that cannot be *cured* by any means at all, cases where it is impossible to put the law of *similars* into action, just because they are cases to which no drug is known to be *similar*. All that is aimed at when such measures are resorted to, is *temporary relief*; and this, whenever it is obtained, is only secured at some cost to the patient."

The previous statement of the editor does not at all confine the use by homœopaths of allopathic medicines to cases where *temporary relief* only is required. His later statement, however, is a perfectly clear acknowledgement that medicines in allopathic doses will give relief after homœopathic infinitesimals have failed, and, therefore, that practitioners who profess to believe that medicine in such quantities is rank poison should, nevertheless, so prescribe it without giving allopathy the credit whenever the infinitesimals or similars are found to be usless.—Ed. M. P. & C.]

ADVERTISEMENTS OF MEDICAL BOOKS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The action of the Royal College of Surgeons of England seems to me as puerile as it is useless, and I am glad to see you have admitted letters on the subject. Not requiring to advertise myself, I can be impartial. The particular case that gave rise to the motion was, no doubt, a gross one; but this differs vastly from the advertisements of books by respectable publishers. It will be impossible to prevent houses like Longmans, Murray, and others exercising their own judgment as to how to sell their books. Why, then, attempt to trammel Medical and scientific publishers like Churchill, Macmillan, Baillière, or Hardwicke?

The folly of the College is the more remarkable when we remember that they do not prosecute those who placard the urinals of London with indecent advertisements, in which the initials M.R.C.S. often appear.

Yours,

Common Sense.

◆

THE DEATH OF NAPOLEON III.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I confess to amazement at the statements contained in the record of the autopsy on the late Emperor Napoleon III., as reported in your last.

If it be impossible to detect kidney disease so advanced as that described, why are all our teachers so constantly urging the necessity of being on the look-out for such lesions? What is the use of chemistry if its easiest clinical tests are thus declared useless? Above all, what is the good of buying a microscope and examining with it the urine of half our patients? If the disease were not suspected, why not have said so? It is too bad to put forth such statements in a document read by every one.

Yours obediently,

A Physician.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—You have done well to publish the account of the French Medical attendants of their late Emperor, and I congratulate you on being the first to issue the statement, and thus indirectly rebuke those of your contemporaries who thought the occasion one to glorify English or disparage French surgery. Science is of no nation, and such rivalry ought not to appear. One cannot believe the eminent men actually engaged desired thus to exult, and it shows great want of taste to express such notions.

To my mind the French report is most valuable. It completely sets aside Sir W. Gull's uncalled-for separate report on a subject on which he very likely has no grounds for the opinion he has ventured to express.

Yours,

M.D.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I quite agree with the writer of one of the "Notes" in your journal to-day on the unsatisfactory way in which the precise cause of the Emperor Napoleon's sudden death is left. The statements of the doctors after the autopsy do not at all clear up the mystery. It is a subject of regret that the cause was not found to be what was erroneously suspected, viz., *embolism*. As it is, I think no other conclusion can be arrived at than that the patient died from *exhaustion*, which might have been the result of a too long fast!

Upon reading the account of the periodical visits of the several doctors during the night immediately preceding the Emperor's death, I, as an experienced nurse in the sick room, may be excused for having thought that one good female attendant, who would have administered nourishment or mild stimulants during those long hours, would have done more to prolong the patient's life than those Medical men, who merely looked at the sleeping figure (which appeared to be in a sound sleep) and did nothing, till a *change* alarmed the household, and then stimulants were freely administered, but too late! We hear of a strong opiate having been administered to lull the pain: has this any connection with the "failing of the heart's action"? But that expression, like the term "convulsions," ought not to be accepted as a *cause* of death; it is a symptom of some remoter cause. If a coroner's inquest had been held in this case, I think a proper verdict would be "syncope from too long abstinence from food;" and when we take into consideration the depressing effects of pain and the fear of successive operations upon an already sorely-tried constitution, it is easy to understand that such a patient required to be kept up during the night with suitable nourishment, combined with mild stimulants, and that even *sleep*, however refreshing under ordinary circumstances, could not sufficiently compensate for the exhaustion that had been going on, and the cruel demands upon the strength and nerve of the patient.

Yours truly,

——.

THE REPRESENTATION OF THE IRISH COLLEGE OF SURGEONS IN THE MEDICAL COUNCIL.

We have reason to believe that the opinion of the law advisers of the College as to the points we have raised regarding the validity of Mr. Hargrave's election will be presented to the Council at its meeting to-morrow.

The Council has certainly taken the proper course in satisfying itself, on indisputable authority, as to the *locus standi* of their representative, and in setting at rest, as soon as possible, questions which seriously affected the status of the College in the Medical Council.

Should their law advisers be of opinion that Mr. Hargrave's tenancy is strictly legal, it will then be the duty of the Council to express its opinion as to the capability of Mr. Hargrave to do justice to the Collegiate interests as spokesman for the Council. If, on the other hand, the legal opinion should be adverse to the validity of the election, it will devolve upon the Council without delay to proceed to the election of a representative in legal form, and Mr. Hargrave, should he desire to present himself, will be eligible. In this contingency we think the Council is bound to consider and guard against the possibility of a future representative holding office without re-election for a longer term than the Council itself may live. We think it would be prudent that an understanding should be arrived at that any Fellow accepting the office should undertake to present his resignation of it to the President of the Medical Council, whenever he might be called upon to do so by the Council of the College. It is remotely possible that under the provisions of the Medical Act a representative might, unless so pledged, set the Council at defiance, and continue, in name, to represent the Council after he had ceased actually to express their views.

Medical News.

Royal College of Surgeons of England.—The following gentlemen passed their primary examinations in anatomy and physiology at a meeting of the Court of Examiners on the 15th inst., and, when eligible, they will be admitted to the pass examination:—Messrs. Henry A. Lovett, Walter C. Morris, Benjamin Jones, John F. Breach, Herbert Duke, and Joseph B. Richardson, students of Guy's Hospital; Harry Lupton, Charles M'Callum, Eugene Crétin, E. Fairweather Luke, and Alfred E. Prockter, of St. Bartholomew's Hospital; A. Bernard Kelly, David Lloyd, and G. Wilkinson Pyburn, of University College; John T. Appleby, of the Manchester School; William Hindhaugh, of the Newcastle School; Peter Bruce, of the Middlesex Hospital; Henry Donaldson, of the Charing Cross Hospital; William Vernon, of the Glasgow School; Frederick H. Kyngdon, and Thomas D. Davis, of the London Hospital; Robert Robinson, of St. Mary's Hospital; and Charles F. Knox, of St. George's Hospital. Thirteen candidates having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their anatomical studies for three months.

Apothecaries' Hall of England.—At Courts of Examiners holden on the 9th and 16th inst. the following gentlemen, having passed the necessary examinations, received the L.S.A. diploma, viz.:—Messrs. Corneby Austin, of 115 Gower Street; Wm. Richard Cumming, of East Acton; H. J. Frith Groves, of Dorchester; Walter Edward Hacon, of Mare Street, Hackney; George Keer, of Wickham Market; Rees Ralph Llewellyn, of Whitechapel Road; and William Allen May, of Colney Hatch; and Messrs. Harold M. Powell, and Frederick William Saberton, both of Guy's Hospital, passed the primary professional examination; and the following as assistants in compounding and dispensing, viz.:—Messrs. George Claridge Druce, of Northampton; John Newton Place, of Spencer Street, Canonbury; William Henry Roberts, of Major Road, Jamaica Road; and Arthur John Rayson, of Yoxford, Suffolk.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this request.

All communications intended for insertion must bear the name and address of the writer; not necessarily for publication, but as a voucher of good faith.

Subscriptions in the United States.—A correspondent has drawn our attention to the fact, that some of the houses in the United States are charging the enormous figure of 15 dollars per annum (more than £3) for supplying this Journal to different parts of the States. We beg, therefore, to state that we shall be happy to supply the same regularly, post free, per annum, if paid in advance, for considerably less than half this amount, viz., six and-a-half dollars (about £1 6s. 0d.), either direct from our offices in this country, or through our recognised agents in the United States.

Notice to Subscribers.—Subscribers who desire to avail themselves of the reduced tariff, by paying for the year in advance, must please send in their subscriptions before the end of the present month, otherwise the usual rate for credit will be charged.

Dr. Johnston Scott.—Your "Notes on Vaccino-Syphilis" will appear in an early number.

Law Respecting Periodicals, Newspapers, &c.—1. Subscribers who do not give express notice to the contrary, are considered as wishing to continue their subscriptions; 2. If subscribers order the discontinuance of their periodicals or newspapers, the publisher or publishers may continue to send them until all arrears are paid up, and subscribers are held responsible for all numbers sent; 3. If subscribers neglect or refuse to take the periodicals or newspapers from the office to which they are directed, they are held responsible till they have settled their bills. Sending numbers back, or leaving them in the office, is not such notice of discontinuance as the law requires; 4. If subscribers remove to other places without informing the publisher, and their periodicals or newspapers are sent to the former directions, they are held responsible.

THE FUND ON BEHALF OF MR. ISAAC BAKER BROWN.

To the Editor of the "Medical Press and Circular."

Sir,—In the early part of last year an appeal was made to the members of the Medical Profession on behalf of Mr. Isaac Baker Brown who was then in great pecuniary difficulties and suffering from an attack of apparently incurable paralysis. The Profession nobly and generously responded to this appeal, and placed at my disposal the handsome sum of £404 10s. 6d. to be expended as I thought best for Mr. Brown's benefit. I am now desirous of laying before the subscribers an account of the trusteeship with which I was honoured, and to give some particulars as to the expenditure of this money. In the first instance it was unavoidably necessary to release Mr. Brown from some pressing liabilities with which he was hampered. This absorbed about £50 of the fund. I afterwards allowed him two guineas per week for his maintenance. After a few weeks it was thought desirable for him, in consequence of excessive bodily illness, to leave London for the country, and accordingly, at his own request, he resided for some time in an hydropathic establishment at Beulah Spa. This entailed an expenditure of three guineas per week. On his return to London, at the end of the summer, I continued to allow him this sum, under the belief entertained by myself and other Medical friends who saw and examined him that, considering the acute character of his cerebral illness his life could not be of long duration. Under these circumstances I considered that I was only carrying out the wishes of the subscribers by liberally supplying him with all the substantial necessaries of life, as well as a few comforts that his state of severe mental and bodily prostration rendered essentially necessary. Since Mr. Brown has been relieved from the pressure of want and all its accompanying anxieties, his bodily health has improved, although he is still paralyzed and requires the constant assistance of a nurse, being unable to stand alone, dress, or feed himself. In fact, he is nearly as helpless as a new-born child. Taking into consideration the probable duration of his life, consequent upon the improvement that has taken place in his general health, I have suggested to Mrs. Brown the necessity of curtailing the expenditure, and allowing him out of the fund two instead of three guineas per week. To this she has consented. After taking into account a few subscriptions which remain unpaid, and deducting a small sum which was expended in collecting the money, and advertising the list of subscribers, there is now a balance in hand of £219 3s. 10.

Mr. and Mrs. Brown (whom I saw yesterday) are full of gratitude to those friends who so kindly came forward to their relief in the hour of their bitter distress. Personally, I desire to express my sense of the great obligation under which the subscribers have laid me, and to thank them for so liberally assisting in this work of Christian charity.

Your obedient servant,
Forbes Winslow, M.D.

Cavendish Square, London,
Jan. 18th, 1873.

APPOINTMENTS.

Adams, W., F.R.C.S.E., Consulting Surgeon to the National Orthopædic Hospital, Great Portland Street, W.

Beck, M., M.B., F.R.C.S.E., an Assistant-Surgeon to University College Hospital.

Carson, A. T., M.D., Medical Officer for the Portrush District of the Coleraine Union.

Farren, N., L.R.C.P.Ed., L.F.P. & S. Glas., Medical Attendant to the Royal Irish Constabulary at Buncrana.

Ford, T. H., L.R.C.P.Ed., House-Surgeon to the Leith Hospital.

Garrard, W. A., L.S.A.L., reappointed Assistant House-Surgeon to the Derbyshire General Infirmary, Derby, for six months.

Gillard, R., M.R.C.S.E., Medical Officer for District No. 7 of the Parish of St. Mary, Lambeth.

Gowers, W. R., M.D., an Assistant-Physician to University College Hospital.

Gregory, J., L.R.C.P.Ed., Surgeon for the Rusholme and Moss-side District of the Chorlton-upon-Medlock Dispensary, Manchester.

Jones, T., M.B., M.R.C.S.E., Senior House-Surgeon to the Royal Infirmary, Manchester.

Kingsford, Mr. P., Junior Resident Medical Officer to the Royal Free Hospital.

Little, W. J., M.D., M.R.C.P.L., Consulting Physician to the National Orthopædic Hospital, Great Portland Street, W.

Lyell, R. W., M.D., M.R.C.S.E., Junior House-Surgeon to the Royal Infirmary, Manchester.

Parmiter, H. R., M.R.C.S.E., Medical Officer for the Winfrith District of the Wareham and Purbeck Union.

Pearson, J., M.D., Medical Officer of Health for the Urban Sanitary District of Maryport, Cumberland.

Prince, J. E., M.R.C.S.E., Medical Officer of Health for the Hill District of the Crickhowel Rural Sanitary District.

Po[illegible], H. C., M.R.C.S.E. (*pro tem.*), Medical Tutor and Joint Demonstrator of Anatomy at Queen's College, Birmingham.

Su[illegible], J. M., M.D., M.R.C.P.L., Medical Officer of Health for the Urban Sanitary District, Oldham.

Tw[illegible], J., M.R.C.S.E., Assistant Medical Officer, Skin Department, University College Hospital.

T[illegible], F., M.B., C.M., House-Surgeon to the Clinical Hospital and Dispensary for Children, Manchester.

W[illegible], T., M.R.C.S.E., Medical Officer of Health for the Rural Sanitary District, Cheadle, Staffordshire.

W[illegible], Mr. G. W., Public Analyst for Plumstead, Kent.

The following promotions in Her Majesty's Indian Army were officially gazetted on Friday last:—

BENGAL ARMY.

To be Surgeons Major—Surgeons S. C. Townsend, W. B. Beatson, M.D., C. T. Paske, W. F. B Dalzel, S. B. Partridge.

MADRAS ARMY.

Assistant-Surgeon D. Kearney, to be Surgeon.

BOMBAY ARMY.

To be Surgeons Major—Surgeons M. M. Mackenzie, A. M. Rogers.

◆

VACANCIES.

Charing-cross Hospital. Assistant Physician or Surgeon in the Skin Department. Honorary.

University of London. Assistant Registrar and Librarian. Salary £500 per annum, subject to annual re-election. Applications, stating age and previous occupation, to be sent to the Registrar at the University offices.

Bolton Infirmary. Senior and Junior House Surgeons. Salary £120 and £100 respectively, increasing £10 yearly. Board and residence. Applications to the Secretary.

Nottingham. Medical Officer of Health for the Borough. Applications for particulars to be addressed to Mr. S. G. Johnson, Town Clerk.

Stockton-on-Tees Dispensary. Apothecary. Salary £120, non-resident Applications to the Honorary Treasurer.

Brighton and Hove Lying-in Institution. House Surgeon. Salary £100 per annum, with residence. Applications to the Chairman of Committee.

St. Mary's Hospital for Women, Manchester. Resident Medical Officer. Salary £60 per annum, with board. Application to the Secretary.

North Wales Lunatic Asylum. Assistant Medical Officer. Salary £100, with board and residence. Applications to the Chairman of Committee, Denbigh.

Borough of Bolton. Medical Officer of Health. Salary £200 per annum. Applications to the Town Clerk.

Sheffield General Infirmary. Assistant House-Surgeon. Salary £65 per annum, with board and residence.

Dunfanaghy Union, Crossroads Dispensary District. Medical Officer. Salary £100 per annum, exclusive of fees. (See advt.)

INDIAN MEDICAL SERVICE.

NOTICE is HEREBY GIVEN, that an EXAMINATION of CANDIDATES for appointments as Assistant Surgeons in Her Majesty's Indian Medical Service will be held at Burlington House, London, on the 17th February, 1873.

Copies of the Regulations for the Examination of Candidates, together with information regarding pay and retiring allowances of Indian Medical Officers may be obtained on application at the Military Department, India Office, Westminster, S.W.

T. T. PEARS, Major-General,
Military Secretary.

Military Department, India Office,
8th January, 1873.

DUNFANAGHY UNION, CROSSROADS DISPENSARY DISTRICT.

MEDICAL OFFICER WANTED.

THE COMMITTEE of MANAGEMENT of the CROSSROADS DISPENSARY will, at their Meeting on WEDNESDAY, the 5th of February, at 12 o'clock, in accordance with the sealed order of the Local Government Board, proceed to elect a SECOND MEDICAL OFFICER for said District, at a Salary of £100 per annum, exclusive of Vaccination and Registration fees.

Testimonials as to character and competency to be lodged with the Honorary Secretary, before the day of Election.

Personal attendance of Candidates necessary, and the person elected must reside at Falcaragh, or immediate neighbourhood.

Application to be made to the,
Rev. V. P. GRIFFITH, Hon. Sec.
Falcaragh, Letterkenny, January 16th, 1873.

NOTICE OF EXAMINATION OF CANDIDATES FOR THE NAVAL MEDICAL SERVICE.

NOTICE is HEREBY GIVEN that a COMPETITIVE EXAMINATION of Candidates for admission into the MEDICAL SERVICE of the ROYAL NAVY, will take place at the University of London, Burlington Gardens, on MONDAY, 17th Feb., 1873, and following days, at 10 o'clock.

Candidates must present themselves at this Department on Thursday, 13th February, 1873, bringing with them the various Certificates of Qualifications specified in the Regulations of the 24th June, 1871, when, should they be found in all respects eligible, they will be permitted to appear for Examination.

A. ARMSTRONG, Director-General.

Naval Medical Department, Admiralty, Somerset House, W.C.,
January 6th, 1873.

THE HOSPITAL FOR WOMEN, SOHO SQUARE.

A Course of LECTURES will be delivered at the Hospital during the months of January, February, and March, 1873.

Dr. ALFRED MEADOWS will lecture on "Fibroid Tumours of the Uterus," on Thursdays, January 16th and 23rd.

Dr. HEYWOOD SMITH, on "Cancer Uteri" on Thursdays, January 30th and February 6th.

Mr. CHRISTOPHER HEATH, on "Diseases of the Female Urinary Organs" on Thursdays, February 13th and 20th.

Dr. ARTHUR W. EDIS, on "Miscarriages" on Thursdays, February 27th and March 6th.

Dr. SQUAREY, on "Ovaritis and Ovarian Dysmenorrhœa" on Thursdays, March 13th and 28th.

Each Lecture will commence at 8.30 P.M. Gentlemen proposing to attend can obtain Cards of Admission on application to HENRY B. INGRAM, Secretary.

THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.

PATRON:—H.R.H THE PRINCE OF WALES.

This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develope the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £35 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote.

Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c., can be had at the office,

40 MOLESWORTH STREET, DUBLIN,
W. O'NEILL, Secretary.

THE EARL STREET MEDICAL AND DRUG HALL.

J. LEONARD and CO. beg to inform the Medical Profession and Public in general that they have become Proprietors of the above old established Concern, recently in the possession of the late Mr. J. King.

In addition to the usual supply of Drugs and Family Requisites for which this Establishment has been long celebrated, J. L. and Co. have the pleasure to announce that, being Licentiate Apothecaries, they have opened a Compounding Department for the dispensing of Prescriptions under their own immediate supervision, with Medicines of the purest quality, and they trust that this arrangement will be found a great convenience not only to the numerous customers of the Establishment, but also to the inhabitants of the north side of the City.

May 8, 1872. 19 NORTH EARL STREET, DUBLIN

QUININE WINE,

AS SUPPLIED TO THE SICK AND WOUNDED DURING THE LATE WAR.

THE many and expensive forms in which this well known medicine is administered too often preclude its adoption as a general tonic. The success which has attended WATERS'S QUININE WINE arises from its careful preparation by the manufacturer. Each wine-glassful contains sufficient Quinine to make it an excellent restorative to the weak. It behoves the public to see that they have Waters's Quinine Wine, for the result of Chancery proceedings, a short time since, elicited the fact that at least one unprincipled imitator did not use Quinine in the manufacture of his wine. All grocers sell Waters's Quinine Wine at 30s. per dozen.

EVANS' EXTRACT OF MALT.

This PURE Preparation of Malt, combined with the aromatic bitter of the Hop, possesses in a most remarkable degree the elements admirably adapted for yielding

NUTRITION TO PERSONS OF
CONSTITUTIONAL DEBILITY,
OR THOSE SUFFERING FROM LOSS OF APPETITE,
OR FROM ENFEEBLED DIGESTION.

Dr. Apjohn in his analysis states—"Of its constituents the most remarkable are those which *include Nitrogen*, the amount of which is unusually large—reaching as it does nearly 5 per cent. The *Proteinic* compounds in an ounce of it weigh 21·32 grains, and the analogous compounds in an ounce of beef-steak 98·48 grains. Hence, weight for weight, the *alimentary value* of the Extract is very nearly one-quarter that of the beef-steak. It is, therefore, *nutritious in a high degree, and being no doubt easy of assimilation, it must constitute an useful supplementary food in cases of debility and weak digestion.*"

Mr. Tichborne writes—"It is particularly rich in the *phosphates*, the value of which, from a *nutritive* or *medicinal* point of view, is becoming more palpable every day. Other preparations of this class which I have examined, on evaporation, yielded only 36 grains of Extractive to the fluid ounce, whilst yours contain 101·5 grains.

Prepared only by

INJURIES OF THE SPINE, THE RESULT OF RAILWAY CONCUSSIONS.

BY J. MORGAN, M.D., F.R.C.S.I.,

Surgeon to Mercer's Hospital, and Lecturer on Surgical and Descriptive Anatomy R.C.S.I., &c.

(*Continued from page* 63.)

WE have in these two cases remarkably confirmatory observations on the condition of the optic papilla, though one subject suffered so much more from general nervous shock and symptoms of urgency sooner than the other. This patient gradually recovered the general command over the muscles; the eye remains in much the same condition. He still dreads some muscular movements, and such an effort as going down stairs, is particularly inconvenient and distressing, and quite unnerves him; his speech is partially recovered; he still says he cannot work, which I am quite sure is true.

There is no doubt, some caution is to be exercised in the analysis of such injuries, as detailed by claimants for damages received by accident; but when we see distinct phenomena develope themselves with a certain regularity, and observe their culmination in the establishment of certain grave and permanent deficiencies of mind and body, such cases are entitled to more than ordinary consideration, and require an extremely guarded prognosis.

In the case of the Medical man who was injured in May, 1871, I have been kindly furnished by him, within the last few days, with the following very interesting and faithful review of his symptoms, as indicated by the effect on the various organs of the body. His description evidences the reception of a jar or concussion to the nervous centres, and the varying influences exercised, even at this interval of time. I look on this account as most important, and remarkably confirmatory of the serious yet subtle effects of these injuries. He thus reviews his condition, past and present:—

"I have adopted a regular order, and describe as closely as I can my sensations, and the effects of the injury

"*On the Memory.*—I had always to write down messages. Could not, for nine or ten months after the accident, be clear in figures, especially with money. On one occasion I almost left myself without money enough to pay the steamboat fare, from not being able to tot up what money I had. I lost the power of telling how distant, in yards, any object was, which I could do very accurately before the accident.

"*On the Thoughts.*—Even now I cannot read with benefit for more than two consecutive hours, and have to read anything of importance several times to get the sense of it.

"*On the Temper.*—I had to keep a constant check for fear of saying rude things, or being cross over trifles, such as drumming on the table or floor, closing doors, the crying of cats, piano practice being highly offensive; and I could not enjoy concerts as I could before, for my hearing became so exalted that false singing was frightful torture, barrel organs were specially so.

"*On Sleep.*—It was fitful and in snatches, without any feeling of refreshment, generally waking as I did for months, a little before dawn, compelling one to read or get up to avoid the tedium of lying in bed.

"*On the Head.*—I felt hot, with lightness, giddiness, and *confusion;* loud noises like rowing, ringing, and rushing, like the sea in a gale.

"*On the Sight.*—Alteration took place in the focal distance—that is, having to walk up to, and examine any object to know what it was; before the accident such an action quite unnecessary. Muscæ volitantes continued for eighteen months, and very vivid spectra; looking at a spot of red the size of a shilling, in a second I would see a ring of bright green, two inches in diameter, round it. I had almost photophobia, and sunshine on my face was very painful. I frown more since the accident than before.

"*On the Hearing.*—It became over sensitive and acute; I could overhear conversations in rooms underneath, or in next house which I could not hear before, and whispering was as distinguishable to me as an ordinary tone of voice.

Any sudden noise was frightful; it would make me jump up, tremble, and sweat as if I was in a hot bath. I could hear my own watch, which has not a very loud one, tick in an adjoining room quite distinctly, and recognise friends' voices coming down a road at some distance, when my people would not believe they were coming at all. Letting a load of stones fall out of a cart on a road nearly finished me once about two months after the accident; it distressed me so much, not seeing it happen, that I cried for half an hour. Now I would not mind as much, if a house fell down.

"*On the Sense of Touch.*—I used to take twice as long to dress myself, and felt confused about buttons; I often had to get myself buttoned by others.

"*On the Attitude.*—It got stiff and unbending, like a man balancing a basket on his head with a heavy weight. My head used to feel as if it weighed a couple of tons at least. I had great difficulty in walking round a corner, and had always to *tack like a ship.* Antero-posterior movements were very painful of the neck; rotation very painful; the rattling motion of a train or carriage was very distressing. I had also great difficulty of picking anything up; I nearly always fell if I could not get any one to pick it up for me. I could not get up without the use of my hands if I laid horizontally. If I was blindfolded and told to walk forward I would fall on my face. My nerve was entirely gone; I could not look over heights or steep places without great pain and fear. Before, I could climb anywhere I could get a hold for foot or hand.

"*On the State of Spine.*—My lower cervical and middle dorsal vertebræ were very painful; sensation on the back of neck very painful. Spinal column I used as if it was one piece. If my hand was taken by a bystander and moved about, it caused the greatest pain *and dread* to me, as if it was to be pulled off with the least touch. After walking or any fatigue to arms or legs, such as rowing or carrying a shawl or basket, great numbness and difficulty in setting the muscles in motion, as if they had got *rusty.* The BRUIT MUSCULAIRE was audibly present to me for months if I was in a quiet place, especially in the muscles of the neck, and shoulders, and arms. I could hear the muscles contracting when I closed my hand in a quiet room. Great sense of *weakness* and *rustiness* in all my joints, such as knees, ankles, elbows, and wrists.

"*On the Gait.*—It was unsteady; I generally used a stick for months; straddled greatly, and wore the heels off my boots in no time, not being able to lift them; going up or down hill was very trying and distressing; sensation in the limbs exalted, and since the accident I am most keenly sensitive to currents of cold air or draughts; feet were generally cold, even with exercise, for a long time—eighteen months—after accident. If I let my feet get very cold the suffering was dreadful, and great difficulty in warming them again. Coming on evening in July and August always felt chilly and damp, and I had to wear warm trousers and a thick pea-jacket. Extensor muscles very painful, especially on part of the thigh, which moved in a very jerky, *rusty* manner. Even now I cannot grasp things firmly or as long as I once could in certain positions of the hand, such as holding a drawing-board or heavy slate perpendicular. Cramps came on, so that I had to let the book or object fall or lay it down. The limbs on the left side of the body did not waste as much as those on the right, and I used to be able to hold out at arm's length a 28 lb. weight with ease. If I were to do it now the pain and *fatigue* of the muscles would make me remember it for some time. Small of my back now weaker than I ever knew it in my life, as I used to be thick and strong then. If I lift a heavy weight now, requiring the use of the entire body, muscles of arms, back, and legs tremble *like leaves.* After the exertion *I can feel the shape, as well as origin and insertion, of all the muscles used.*

"*The Pulse* is slow and weak decidedly. For some four months after the smash I used in my sleep to lie in the *prone* position; I would go to sleep on my right side, as is my custom, and always woke on my face. A high pillow is a great comfort; if I used a low one I always got cramps in the neck."

The contrast of the general symptoms, as well as of those affecting the muscles more particularly, is remarkable; in one case there is constant muscular tremor, and in the other the peculiar exaltation of "muscular sense," with general impairment of power still existing after a lapse of nearly two years.

(*To be continued.*)

◆

NOTES OF A CASE OF VACCINO-SYPHILIS.

By J. M. Johnston Scott, M.D.

I send you some notes of a very interesting and peculiar case of Infantile Syphilis, which came under the care of Dr. H. S. Purdon, at the Hospital for Diseases of the Skin, Belfast.

Thomas Harrison, a well-nourished, and very pretty child, was brought to the above-named institution by his mother, on the 9th November, 1872. Her account of the child and its malady was as follows:—"The baby was in perfect health from the time of its birth (ten months ago) up till the third month, when it was vaccinated. The pock was developing in the usual way, when an eruption made its appearance on the arm, near the vesicle, and over the whole body." This she described as being little "watery blisters," which were a little "itchy."

When we first saw him his body, arms, and head were covered with a bullous eruption, which was very copious on the body, where the bullæ were the size of a shilling-piece, and also on the head and forehead, where they were much smaller, being about the size of a threepenny-piece, while a few still smaller in size were observed on the ankles and toes of both feet, and also a solitary one on each ear. The pock at the time we first saw him was an open ulcer, circular in form, and about an inch in diameter, with raised edges, and an indurated base. It will be remarked that this was fully six months after the child had been vaccinated, and in the meantime the ulcer had shown no tendency towards repair, and almost none towards extension.

We also learned that another eruption had existed some time before he was brought to the hospital, and of which we could still find some traces in the shape of "cooked ham" coloured maculæ.

There were no mucous patches at the mouth, nose, or anus, but around the latter part the eruption was plentiful and well marked. The bullæ were well marked and distinct, circular in form, and contained a clear serous fluid, which on rupture or drying, left a perfectly flat greenish black scab; showing no tendency to ulcerate; we may remark *en passant* that the bullous is one of the rarest forms of syphilide.

Dr. Purdon, on examining the child, ordered him aperient powders, and citrine ointment with carron oil. On the 17th, as the former medicine had not produced any amelioration of his condition, he was ordered iron wine and Fowler's solution; on the 27th, from the appearance of the eruption, which was now better developed, he was ordered mercury with chalk in one-grain doses at night, from which time he improved so rapidly that he was discharged completely free from the eruption on the 1st of January, 1873.

There cannot be any doubt as to the syphilitic nature of the above disease, when we take into consideration the character of the eruptions, the marked improvement which took place when mercury was exhibited; the peculiar characters of the cicatrices left behind, and the salmon discolourations which we found wherever there had been a spot of disease.

The suspicion of its being a case of hereditary syphilis is untenable, because we have no history of any syphilitic taint in any member of the child's family. The father and mother are healthy, neither of them ever had any eruption. The mother never had a miscarriage, her seven other children are alive and healthy, and the subject of these notes was equally so up to the time he was vaccinated.

Nor had our patient, when brought to us, the characteristic cachectic appearance of hereditary syphilis, while the state of the pock, its indurated base and permanence in the absence of treatment, point plainly to its being the place of implantation of the virus.

It is curious to notice the difference in the duration of the incubation of the two diseases. The vaccinia had advanced to a considerable degree before the effects of the syphilitic virus which was implanted at the same time made their appearance.

Not the least interesting point in this case is that we are shut up to the belief that the syphilis was introduced into the child's system by the use of impure vaccine lymph taken from the body of a person tainted with syphilis.

And I am induced to send you these notes, because I am aware that the existence of this as a cause of syphilis has been, and still is, denied by many; and that, notwithstanding the evidence of Dr. Pacchiotti, of Turin, the historian of the epidemic of syphilis, which produced such disastrous results amongst the children of the valleys of Rivalta, in Piedmont, in the year 1861.

Dr. Whitehead, quoted by Tanner, writes that he has seen several cases of infantile syphilis brought about by impure vaccine lymph, while many writers on syphilis and on vaccination, agree with Viennois, that syphilis may be propagated by vaccination, but that it only occurs where blood has been taken along with the lymph from the arm of a syphilitic patient.

As to the propriety of administering mercury to young children suffering from the ravages of syphilis; many and diverse opinions are held at the present time among Medical men.

Some authorities interdict the use of mercury in this case, and state that under no conditions whatever would they venture to administer this drug to infants or young children, while others assert quite as firmly that it is not only useful but indispensable; among whom I may mention Dr. McCall-Anderson, who, in his latest work on the "Treatment of Diseases of the Skin," says there is no other treatment which appears to have any material influence on the disease.

Another section would not give the drug directly to the child, but would affect it through the mother, while the most extreme party of all asserts that by the use of mercury we may eradicate the syphilitic virus from the system if the case be taken in time, that is, before the virus has had time to produce a profound cachexia.

Those authorities who prescribe mercury for children order it, as a rule, in the form of mercurial ointment, directing it to be firmly rubbed into the skin; and state that by so doing they obtain more satisfactory matter than if it were administered by the mouth; and, as a rule, this will, we think, be found the better plan of the two.

But in a case like that detailed above, where the eruption involves a large area of the cutaneous surface, and where the remaining skin is irritable from the effects of the virus, such treatment, if persevered in, will most probably result in an eczema mercuriale.

In the above case our treatment produced a diarrhœa, which for a few days interfered with and retarded the progress of the cure, but this was checked by the use of chalk, after which we resumed the mercurial.

◆

CASES IN MILITARY PRACTICE.

By **Mark Anthony**, M.D., 47th Regiment, Carlisle.

APHASIA.

Whilst serving abroad some short time ago, I find from my note-book the case prefaced as above, and the following ones, which for interest and peculiarity are deserving of some attention:—

Private M——, 53rd Regiment, æt. 32, was admitted into hospital on 18th May, 1871, with the following symptoms:—Is unable to articulate or make himself understood; has great confusion of ideas; cannot read or write (though previous to seizure could do both); suffers no pain, but by pointing to left side of head; indicates some uneasiness in that locality; both pupils are natural; tongue foul; bowels irregular, and the pulse at both wrists beating regularly and naturally. He understands everything that is said to him, but his endeavours to reply are pitiful in the extreme. He has forgotten the names of places and things. No paralysis or disease of heart, and his urine is natural in quantity, and shows no traces of albumen. Eats and sleeps well.

His previous history is as follows:—Has always been healthy and sober in habits; has served in India for several years, where he enjoyed good health, save when at one time he had enlargement of spleen. On the day before admission had been on duty when he got a chill, and immediately afterwards felt a numbing sensation over left side, beginning at left temple; that evening was attacked by symptoms already indicated. The treatment adopted was at first calomel and pulv. jalap comp., and subsequently iodide of potassium with quinine, together with a mild and unstimulating diet. Under this treatment he recovered so far as to be able to recount in a sort of way his symptoms and the period of attack. There are still, however, words he cannot pronounce or spell correctly.

He remained in hospital one month, when, owing to his being sent with other invalids to England, I lost sight of his most interesting case.

Unusual as are the number of cases of this peculiar disease which comes under the notice of the physician, yet each one furnishes new matter for thought, and a comparatively open space for theory in the study of aphasia.

Without injury, previous inflammation, or discernible disorder of other organs, a young man is suddenly bereft of all power of expressing his ideas, painfully conscious of his defect, and with unimpaired intellect he becomes dumb.

Since the discovery of Monsieur Broca that the seat of the articulating power of the brain was in the second and third frontal convolutions of the left anterior lobe, much has been done to elucidate the mystery of the aphasic condition. In Private M.'s case the theory was, that an embolism had blocked up the middle cerebral artery, probably from some former undetected disease, either of liver or spleen incurred during his former service in India. In military practice we have often to deal with serious and life-destroying diseases; but, unfortunately, we have also to remember that the most serious disease is often mimicked by ingenious but ungrateful defenders of their country. In considering the present case, this had to be passed in review before arriving at a diagnosis of the disease, falling back for want of something better, and thereby following the example of our professional brothers in law. On circumstantial evidence it was found that every outward circumstance precluded the idea of the man being a malingerer. I regret that the circumstances above mentioned prevented me from following up the case, but I have little doubt, taking all things into consideration, his good general health, his age, and the degree of recovery he exhibited during the short time under my care, when the treatment was merely tentative, with the hope that Nature would re-establish the current of circulation; that eventually he would recover the faculty of speech of which he was so suddenly and with such little apparent cause deprived.

INGUINAL HERNIA REDUCED BY TAXIS AND POSITION.

Was asked by Dr. H——, Civil Practitioner at St. George's, Bermuda, to see the subject of present short description. A middle-aged man, a negro, suffering from rupture of left side, which, though of several years standing, had only become irreducible on the morning of our visit. On examination, we found a large inguinal hernia, which resisted our efforts to reduce it by taxis and warm baths. Before trying the effects of chloroform, we determined to try the effects of gravity on the tumour, in other words, to invert the man as much as possible, with his back leaning against the edge of the bed, his head downwards, nearly resting on the floor, and with my friend, Dr. H., assisting to maintain him in this novel position. I succeeded after very slight manipulation in reducing the rupture, which, whilst the patient lay in the recumbent position, had resisted all our efforts. In describing such a case, I know many objections are capable of being raised to its treatment; but, having effected its purposes, was sufficient to me that there was a something in it, though rough, and in very many cases, inapplicable, it is at least prompted and suggested by a little common reasoning.

ON THE USE OF DRY-POWDERED BLOOD.

By Dr. de Pascale, of Nice.

Several years ago I published from my experience and medical practice, some observations on the very beneficial effect of warm blood taken the moment when extracted from the calf or ox, killed for general domestic use.

I mentioned at that time the cases of three invalids, not English, suffering from hæmoptysis, in whom tubercles were diagnosticated, who derived great benefit from that treatment. The quantity of blood lost by one of the above-mentioned invalids was enormous; but his perseverance for two years or more in drinking daily the blood, made him well and healthy. At this present time he is walking about Nice, or attending to the business of his large establishment.

I do not wish to dwell upon the great improvement in my own general health after drinking the warm blood for about a month. One of the English doctors practising in this place had the opportunity of verifying my improvement, and the experiment which I made, when in a state of general weakness and pallor, in consequence of suffering for many years from malarial fever, taken during the siege of Venice in 1848 and 1849.

Everyone knows the history of those barbarians, who were accustomed to drink the blood of their victims at a feast after their bottles; and also of those who were supported by the blood of their companions, wrecked in the *Medusa* in 1807; and of others who have been nourished in the desert by the blood of animals.

Dioscorides affirms in his *De Medicinali Materia*, that animal blood has been used for the purpose of curing diseases; the old women adopted a similar system.

Finding among the English and American patients in Nice an unconquerable repugnance to such a remedy, the name only having the power of producing nausea, I was obliged to disuse it. But afterwards a dim recollection of the manner in which it was administered by old Medical men in my youth, made me adopt the plan of giving it in the form of dry powder.

History also relates that dry-powdered blood was used before the thirteenth century, when the quack, Jean de Gaddesden, brought it into renown.

It is easy to understand the comparative difference between the warm and the dry blood. In the first there is life with animal heat, and volatile principles, which conduce to assimilation. Notwithstanding, in the dry blood, fibrine, albumir, hæmatozine, manganatic, and ferruginous salts remain.

Between the seventeeth and eighteenth centuries the celebrated anatomist of that time (F. Buischio) found in the blood the necessary elements for the composition of every tissue of our body. At the end of the seventeeth century also was discovered one of the most important principles of the blood, that is iron, by M. Lamey, and afterwards by Berzelius. According to Berzelius, a distinguished professor of chemistry, the blood of the ox is the most similar to that of man; this, in fact, I have used in several cases of general weakness with anæmia, and in cases of chlorosis.

The blood of the ox, after being dried in a water-bath, is reduced into a very fine powder. and grated through a sieve. Dry blood can be taken for any length of time, being almost tasteless, and no repugnance is likely to be felt, as is often the case with raw meat. It can be taken as any common powder, mixed with soups, milk, marmalade, chocolate, or enclosed in a wafer.

In two cases I have given the powdered blood under the name of nutritive powders, mixed with a small quantity of pepsine; choosing that name lest ladies, startled by one more precise, might have difficulty in taking the medicine.

The quantity to be taken may vary according to the age, sex, or the state of health and digestive power of the patient. In general, I begin with thirty grains, which is increased according to circumstances; but quantity must be left to the discretion of the physician who prescribes.

Hospital Reports.

JERVIS-STREET HOSPITAL.

Notes of Cases occurring during December, 1872, *in Dr. Meldon's Clinique.*

(Reported by L. J. Hughes, Resident.)

On Monday, the 29th of December, Dr. Meldon, in his clinical lecture, reviewed the cases treated by him during the month then closing. He remarked that the students of Jervis-Street Hospital have unusual opportunities of becoming acquainted with every variety of accident. Fractures and wounds have been very numerous during the present month; no less than thirty of the latter, and twenty-two of the former, having occurred during Dr. Meldon's term of ten days' duty. Most of the wounds were contused and lacerated—in one it was necessary to tie the ulnar artery, and in another the occipital was cut. Two were cases of punctured wounds—one by a scissors, which pierced the ulnar artery in the centre of the forearm, and which vessel was secured by a double ligature, above and below the bleeding point; the other was that of a sailor, who had been stabbed in the back and side with a penknife, which penetrated to a considerable distance in four places. This man, who refused to remain in the hospital, was dressed, but unfortunately did not return.

In general the sutures used for external patients, have been carbolized catgut. The lacerated wounds were all dressed with charpie saturated in a lotion composed of equal parts of sulphurous acid and glycerine, and which is usually known as Dr. Stapleton's lotion.

The fractures have been much more important, though not so numerous. They included ten cases of Pott's fracture, two compound comminuted fracture of both bones of the leg, three fractures of the thigh, one of which was compound, occurring in a patient who had also a compound comminuted fracture of the forearm, and a Pott's fracture of the other leg.

One case of fractured tibia, that of the French sailor, was worthy of notice from the manner in which it occurred. In this case the fracture was caused by powerful straining of a rope in which the man's leg had somehow got involved, and so was twisted round until it was broken. On admission there was enormous effusion, and apparently great laceration of the surrounding parts. The leg was put up in a box splint, and afterwards in starch, with the happiest result to the patient.

There was another case of compound fractured tibia in the lower third, and a simple fracture of the fibula near the knee, which was also put up in a box splint filled with bran; this can be so arranged as to take the part of pads, and at the same time it acts as an antiseptic. The box splint has many advantages, and can be made to do the part of a Dupuytren by the proper arrangement of pads without in any way sacrificing its own peculiar merits. In this way, by securing the knee a perfect rest for the lower extremity is obtained, whilst a proper application of pads in the case of Pott's fracture is sufficient to obtain the result derived from the use of Dupuytren's appliance. Moreover, it is possible by suspending the box-splint to allow a certain amount of motion without any risk of disturbing the fragments. This, of itself, is very important, having regard to the general health of the patient. The box may be easily suspended a little above the level of the bed, by tying a tape to each of the four corners of a piece of linen, passing under the splint, these may then be passed extending above from one extremity of the bed to the other. This custom ot slinging fractures of the leg was first introduced into Jervis-Street Hospital by the senior surgeon, Dr. Stapleton.

Two cases of compound fractures were followed by tetanus, one of which ended fatally. In this case the patient was not brought to hospital until five days after he had received the extensive injuries, namely a compound fracture of the femur, compound comminuted fracture of the radius and a Pott's fracture. The day of his admission he became the subject of traumatic delirium, of a low muttering character, as also extensive pneumonia. From these, however, he recovered under stimulating treatment. Some days after, owing to extensive bed sores, it became necessary to put him lying on his face, having previously put up the fractures in plaster of Paris. Tetanus set in on the twentieth day after the accident, and terminated fatally in twenty-two hours. In this case some temporary relief was obtained by the inhalation of chloroform. In a *post-mortem* examination it was found that the large branch of the ulnar nerve, which is given off in the forearm (Dorsalis Carpi Ulnaris) had been pierced by a spicula of bone. This, as well as the ulnar itself, was in a congested condition. All through this case the risus sardonicus was badly marked, although the muscles of deglutition, as well as those of mastication, were much affected. Death was from asphyxia.

The second case, that of James Kavanagh, commenced with very acute symptoms; these, however, yielded to treatment, and the patient is now so much improved, that he may be pronounced out of danger. The treatment consisted in the administration internally of large doses of belladonna, conium, and hyoscyamus, at the same time that atropia and small doses of morphia were injected subcutaneously on either side of the spine. It may be remarked, that after each injection the symptoms underwent considerable abatement. At one time, when the disease was most severe, the morphia was omitted, but when it was found that the usual improvement did not follow its injection, the morphia was again added. At a subsequent period the atropia was omitted with like results. Of the other cases of fractures, few observations are necessary. One, an old woman, æt. 90, who sustained a compound comminuted fracture of the leg, died.

There were three cases of dislocations, one compound of the thumb, and two of dislocation of the head of the humerus into the axilla. All these were reduced without trouble.

Of general surgery, there have been many interesting cases; one of necrosis of the femur, on which Dr. Meldon operated early in the month, gave some little trouble, owing to secondary hæmorrhage, which occurred on the seventh day from the anastomatica magna. This was so copious that in a few moments the patient was blanched, and in a state of syncope. It was effectually arrested by plugging the wound with lint, steeped in equal parts of muriated tincture of iron and turpentine. In the same ward we have a well-marked case of iliac, as also one of psoas abscess, from which two and a-half quarts of pus were removed by means of the aspirator. In the female ward, in a case of varicose veins, Dr. Meldon passed needles under the saphena vein, and thereby obtained its obliteration. This may be compared with one similarly affected, in which sometime since he performed the operation known as "Corrigan's operation," and which consists in cutting down on the vein and touching it with nitric acid; the result was also satisfactory.

Several cases of sciatica were cured by the use subcutaneously of atropia and morphia. Dr. Meldon remarked, although these medicines were generally considered antidotal, yet in practice we find that the combination is most useful.

T. B. CURLING, F.R.S., President, in the Chair.

AN ANALYSIS OF SHIP AIR, AND ITS EFFECTS.

BY ALEXANDER RATTRAY, M.D. Edin.,
Surg. R.N., H.M.S. *Britannia*.

(*Communicated by* GEORGE BUSK, F.R.S.)

MUCH, perhaps nine-tenths, of the sickness prevalent in H.M. Navy is preventible. Many diseases result from impure air. Experiment shows that ship air is more vitiated than is generally supposed. No analysis has hitherto been made. Without a correct knowledge of the intensity and nature of pathological agents, we cannot fairly estimate their effects, or endeavour to counteract them.

Measurement showed that in H.M. frigate *Bristol*, the type of a large class, the crew had little more than from 100 to 120 cubic feet space at night and 60 at meals; officers about 400. This contrasts with the 600 cubic feet allowed soldiers in cold and 1,500 in warm climates; hence chiefly why ship air is more impure than that of barracks or private dwellings generally. Although large ironclads give a greater air-space, they are more shut in, and the internal atmosphere is probably equally impure.

The results of 150 experiments, during a four months' voyage from the Cape of Good Hope to England, show that carbonic acid, chiefly derived from the lungs, is the great impurity. This varies from 4 to 18 vols. per 1,000, and even more in the deeper parts. For obvious reasons, it is most abundant where and when the men are crowded—*e.g.*, on the berth-deck, at meal-times, and at night. It also varies with the ventilation.

Ammonia from the urine; sulphuretted hydrogen and sulphide of ammonium from the bilge; volatile organic matter chiefly from the lungs, skin, and mucous membranes; watery vapour from the skin, lungs, and sodden decks; microscopic floating dust or *débris* from the ship, stores, and crew, are also estimated; the quantities being more abundant than is consistent with health. Ozone diminishes as the impurity increases, and is absent in the innermost parts.

The mechanical and chemical pathological effects of carbonic acid are immediate and remote. From nightly renewed imperfect blood aeration follow lung congestion and a predisposition to pulmonary and cardiac ailments, easily excited by the sudden chills of night-work and severe exercise aloft. Hence the frequency of diseases of the respiratory and circulating systems—*e.g.*, phthisis, bronchitis, catarrh, &c. From its non-elimination, and perhaps reabsorption, spring general blood and tissue poisoning, imperfect nutrition and function of every organ and system, whether nervous, muscular, or granular, a long list of more or less obvious, but perhaps oftener obscure ailments, and ultimately premature old age. These results are aided by the long inhalation of organic matter—sulphide of ammonium, &c., and perhaps the deficiency of ozone.

The practical conclusions show the necessity of giving ships the best ventilating apparatus; of always keeping this efficient and at work; and of not trusting solely to fixed systems, but aiding these, when possible, by others; as the air which all, and especially fighting men, breathe cannot be too pure.

◆

THE SURGICAL SOCIETY OF IRELAND.

The Society met on the evening of the 3rd January.

The President of the College of Surgeons, Dr. Kirkpatrick, in the Chair.

(Continuation of the discussion on Mr. Macnamara's communication regarding the "Vermicular Action of the Urethra.")

He (Professor Macnamara) was calling attention to the actions of the urethra on the catheter before it got near the sphincter, which disposed of Mr. Wharton's observation on that point. Reference had been made by Mr. Richardson to the winged catheter. He thought in some cases it was an exceedingly useful instrument, but it was not intended for stricture at all. It was a kind of elastic stem, with a wing at each side, and it was introduced into the bladder in cases of enlarged prostate where it was necessary to pass an instrument continually. He (Mr. Macnamara) did not say that vermicular action would counteract the specific gravity of the instrument when the patient was walking about, and the penis in a depending condition, in which the natural tendency of the instrument was to fall out; it was in these cases they put on the jugum. Dr. McDowell's observations would have great weight, if from the meatus externus to the bladder the whole urethra was in a state of stricture; but they knew as a general rule that the stricture rarely occupied more than one inch, the whole of the remaining eight inches of the urethra being in a normal and healthy condition. He contended that his theory of vermicular action was the most reasonable explanation of the undoubted fact that the tendency of an instrument introduced into the urethra was towards the bladder. If the instruments which had undoubtedly made their way into the bladder, did not reach it by vermicular action, how did they do so?

Mr. **Fleming** suggested that in those cases when an eight or a ten inch staff had been introduced into the bladder, the staff might have driven the portion of catheter remaining in the urethra into the bladder, and thus the whole of the catheter would be found in this viscus.

Professor Macnamara said he was present at an operation where a portion of a catheter was cut out of the bladder, and it was found to be agglutinated together by the mortar-like deposit. It was clear that this could not have been poked in by an instrument a few minutes before, as it would not have had time to agglutinate itself into a mass, almost resembling a stone.

FORCEPS FOR EXTRACTING FOREIGN BODIES FROM THE ŒSOPHAGUS.

Mr. **Stapleton** exhibited an instrument made by Matthieu, of Paris, for extracting foreign bodies from the œsophagus or the stomach. It was made on the model of what were called lazy scissors, or garden scissors for cutting grapes. It was very elastic, easily introduced, and took a very firm hold of any foreign body it grasped; and being rounded at the point could be introduced without danger. Another instrument had been made by Matthieu for the purpose of detecting foreign bodies in the œsophagus. It was eighteen inches long, made of whalebone, and towards its end was covered with ivory knobs, so that if there was anything in the œsophagus, it could be detected by the knobs touching it. A child was recently brought into Jervis Street hospital having swallowed a halfpenny. He got this instrument, and with it was able to percuss the half-penny, and turn it from one side to the other. As from its shape it could not be extracted, they inverted the child, gave it a shake and the coin fell out.

The Society then adjourned.

◆

DUBLIN PATHOLOGICAL SOCIETY.

Dr. **Henry Kennedy** presided at the meeting on Saturday, January 25th.

Dr. **Eames** said the subject of the case which he was about to bring under the notice of the meeting was a compositor, who died on the morning of Friday from bronchitis. He had been twice previously in Mercer's Hospital under his (Dr. Eames') care. When he was before admitted he was somewhat emaciated, the skin and conjunctivæ slightly jaundiced, and dark areolæ under the eyes. There was no cardiac murmur, but his breathing was rapid, owing to the pressure upwards of the fluid in his abdomen, which was greatly distended. The percussion dulness of the liver was diminished, and that of the spleen was not increased. It appeared from the history of the case that the man used to drink raw whiskey in the morning, after ceasing his nightwork. He had vomited blood, and had had piles, but there was no history of syphilis. He suffered occasionally from constipation, and at other times he had diarrhœa. He had slight pains from time to time over the abdomen, and sometimes experienced localised pain over the region of the liver. On both occasions he was relieved by diuretics, purgatives, and the hot-air bath. He was afterwards attacked with bronchitis, and brought to Mercer's Hospital in a dying state, where he succumbed. The autopsy showed evidences of perihepatitis. The liver was small, dense, and not fully cirrhosed, the capsule being thickened; the gland was carnified with fibrous trabeculæ passing through its substance; a large cystic tumour was attached to it below; the gall bladder distended, and the intestines bound together by dense adhesions; spleen small and hard; the right kidney had two small cysts within it, but the left was healthy. The diagnosis was cirrhosis; but the *post-mortem* proved it to have been perihepatitis. The portal vein is in both obstructed, and the results were accounted for by his habit of drinking in the mornings, when probably it was the more readily absorbed by the veins of the stomach and brought to the liver. As for the slightness of the pain over the liver and the absence of tenderness on pressure, the hæmatemesis and piles were sufficient to account for the error in the diagnosis.

The specimen which Dr. **Purser** desired to bring under the notice of the Society was from the body of a woman who had been under his care in the City of Dublin Hospital. She was 35 years of age, unmarried, and came to the hospital early in last summer suffering from the common form of Bright's disease. She remained for some time in hospital, and during that period nothing occurred calling for notice, except that while under treatment the dropsy completely disappeared from the left side of the body, while it still remained on the right. She came back about two months ago, but then had not any dropsy, though still passing albuminous urine. She could retain nothing on her stomach, her tongue was dry and glazed, and she sank from day to day. On opening the chest, the right pleura was found to be full of a rather bright greenish-coloured fluid, perfectly limpid and transparent. In this liquid was found a number of floating cysts, the walls of which were exceedingly thin, so that if it were attempted to lift them up they were immediately broken. They were perfectly transparent, and they appeared not to be very tensely filled with fluid, as when floating they tended to flatten themselves out. He examined these cysts. Their walls were homogeneous or faintly striated, and their inner surface was covered with shining granules, some of which dissolved in acids with effervescence, and others, apparently of a fatty nature, remained grouped in masses, as if they were the remains of degenerated cells. He had looked very carefully into the fluid for hookets or other peculiarities which might be diagnostic of echinococci. There was no trace of inflammation of the pleura. The lung was compressed on that side, though the air was not completely expelled from it. He might mention that during the last four or five days of her illness she was lying altogether on her right side. The diaphragm was healthy, as was also the heart. The abdomen and peritoneum appeared perfectly healthy, and there was no fluid in it. There was no dropsy of the cellular tissue. The liver was very much deformed, and united in places by old adhesions with the diaphragm and the spleen. The surface—particularly the superior—of the liver was marked by deep cicatricial fissures, from many of which the bands of adhesion already mentioned, passed. There were also scattered through the substance of the liver, partly lying in these cicatrices and partly in the unaltered tissue of the liver, round nodules, varying in size from a pea to a marble, of a dull white colour and firm consistence. Under the microscope they presented the ordinary appearance of tissues which had undergone cheesy formation,—viz., small shrivelled cells, fatty granules, and fine distinct fibres. The gall bladder was full, but without any obstruction of the bile duct. The kidneys were large, heavy, and firm, smooth and mottled on the surface. On section they resented the appearances of parenchymatous nephritis, and on the addition of tincture of iodine the vessels became brown. The mucous membrane of the stomach presented a few hæmorrhagic spots, but was otherwise healthy. The pyloric opening was slightly constricted. The other organs were healthy. The uterus was small, and apparently a virgin uterus, and there was no sign of syphilis on any part of the woman's body—either in the bones, skin, or genital organs. From all this it was very difficult to believe that the disease of the liver was syphilitic, and yet it was still more difficult to know what it was if it were not syphilitic. The points calling for observation in this case were—first, the disappearance of dropsy from one side of the body, which was inexplicable, except they assumed some influence of the nervous system on the production or disappearance of dropsy; second, the resemblance of the disease in the liver to that produced by syphilis, yet with the absence of any sign of syphilis in the other organs of the body; and third, the peculiar bodies which were found in the pleura.

Dr. **Hayden** exhibited an example of

MULTIPLE CIRRHOSIS OF THE LUNGS,

resulting from chronic interstitial pneumonia, together with circumscribed and exaggerated vesicular emphysema, compensatory of the former. A man, æt. 43, a pensioner from Her Majesty's Army, who had spent nine years in India, and had, whilst there, fever and ague, was admitted into the Mater Misericordiæ Hospital on the 27th December, 1872. Two years previously his health became deranged, and his respiration embarrassed, with some pain of the chest. Three weeks before the date of admission his feet began to swell. When in hospital his condition was the following:—He was cyanosed; unable to lie down from difficulty of breathing; the lower extremities were œdematous and livid; pulse rapid and feeble; precordial dulness abolished; the heart pulsated behind the ensiform cartilage. Its action was feeble, and its sounds, which were all but completely masked by loud bronchial râles, were free from murmur. The chest walls were generally hyper-resonant, and loud bronchial râles were audible all over it. Expiration was prolonged, and, in short, all the ordinary signs of emphysema existed, with which it is unnecessary to occupy the time of the Society, with one exception, and that had reference to a phenomenon which, in his judgment, had a special diagnostic value. In the lower and back part of the left side, and in the left sub-clavicular region, an auscultatory phenomenon of a peculiar character was heard, both with inspiration and expiration. It might be described as a sibilus, with a metallic quality, and might be conveniently designated as an amphoric sibilus; such a sound as one might suppose produced by blowing through a reed into an empty cask. From this sign he confidently diagnosed localised exaggerated vesicular emphysema. On a former occasion he had the honour of laying before the Society the particulars of a case in which, from the evidences afforded by a similar phenomenon, he made the diagnosis of a corresponding state of the lung, and the morbid specimen he then exhibited to the Society confirmed his diagnosis. The urine was normal, and passed in small quantity. The condition of the man underwent alternate changes of improvement and retrogression. The legs were punctured, and a large quantity of serum was thus evacuated. He sank by a gradual process of asphyxia and failure of the right side of the heart, and died on the 19th of January, 1873. The thoracic viscera were alone examined. The lungs were extensively adherent to the chest walls. The pulmonary pleura on the right side was a quarter of an inch thick, and sent strong fibrous bands from its deep surface into a portion of the lung about its centre. This portion of the organ, about four inches square, was perfectly solid, and when cut into grated [illegible] the knife, was devoid of air, and exhibited in section [illegible] white bands of fibrous tissue, forming a close net-work. Examined under the microscope, this portion of the lung [illegible] a greatly hypertrophied condition of the connective [illegible] with total obliteration of the air-cells. The apex of [illegible] was blown out into something like a bladder as [illegible] clenched hand. This was ex- [illegible] surface corresponding to [illegible] previously described. The base of the left lung [illegible] seat of pneumonia in its first stage. It was solid, [illegible] and readily broken up under pressure. The [illegible] of the inferior lobe formed a bladder-like [illegible] but larger than, that of the right apex, [illegible] lung presented a similar condition [illegible] portions of the lungs [illegible] surrounding surface, were strictly circumscribed, of tympanitic resonance, and fixed in their respective situations. They presented examples of veritable localised vesicular emphysema, consisting of over-inflated air sacs, with partial rupture of the intervening septa. The anterior edges of the lungs, which were likewise emphysematous, over-lay the pericardium, to which they were firmly attached by old adhesions. The lungs were considerably in excess of the normal volume. The trachea and primary bronchi were dilated and congested. The heart was generally dilated and hypertrophied, especially the right ventricle; it weighed eighteen ounces, but was structurally healthy, as were likewise the valves. Dr. Hayden begged to remark in reference to this case, that it was interesting as affording an example of several distinct centres of chronic interstitial pneumonia, followed by hypertrophy and contraction, with limited compensatory emphysema of the lungs. These changes, no doubt, dated from the period of his illness two years previously. The case was, however, especially interesting in a diagnostic sense, as affording an example of an auscultatory phenomenon, which he ventured to regard as pathognomonic of exaggerated and circumscribed vesicular emphysema, and for want of a more convenient term would designate as *amphoric sibilus*. Theoretically, it was not difficult to conceive how this phenomenon was produced. An air tube, of very small calibre, opening abruptly into a large air chamber with membranous walls, would conceivably yield such a sound during the entrance and exit of air correspondingly to inspiration and expiration respectively. The practical value of the sign is, however, of greater importance than the theory of its production; and having now made the diagnosis of the condition of the lung previously mentioned on two several occasions from this sign alone, and having been borne out by the result of *post-mortem* examination in both these cases, he ventures to regard it as pathognomonic of the condition mentioned.

Dr. **Henry Kennedy** made a communication of

A CASE OF ACUTE THESIS,

in which the colon was very extensively engaged.

As our space does not permit of an extension of this report we must postpone the publication of Dr. Kennedy's address until our next issue.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 29, 1873.

THE IRISH COLLEGE OF SURGEONS AND THE MEDICAL COUNCIL.

The opinion of the law advisers of the College was not submitted to the Council of the Royal College of Surgeons in Ireland, as was expected, on Thursday last, and we are, therefore, not accurately aware of the opinion which they entertain as to the legal questions respecting Mr. Hargrave's position as representative of the College. We have, however, taken steps to inform ourselves as to the law on the subject. As our readers are aware, we challenged the legality of Dr. Hargrave's election on the grounds—firstly, that he was appointed three months before the office was vacant, and secondly, that the appointment was extended from one year to five, by an interlineation in the minutes, which materially altered the terms of the original resolution.

On both of these points we believe it will be found that the election was *at the time* distinctly illegal and improper, but it will be held that the Council by permitting Mr. Hargrave to hold office for so long have condoned the original irregularity of the appointment, and could not now succeed in any legal steps to remove him. This condonation does not, however, affect the right of any Fellow of the College to pursue the matter by an application for a writ *quo warranto*, which would in all probability be granted.

We give this *résumé* of what we believe to be the law, being, of course, aware that a resort to legal proceedings could not be necessary if the Council thought fit to express their opinion as to the competency of their representative. Should the opinion of their law advisers coincide with that expressed above, it will devolve upon the Council to act on their own responsibility. We cannot believe that any of its members will be content to sacrifice the interests of the College to their own *mauvaise honte*. There is a certain party in the Council from whom we hardly look for action in the matter, but we must again ask, in the interest of the Fellows, what has become of the reform party who have within the last three years obtained admission to the Council by denouncing abuses and proclaiming purism? Are the Fellows to infer that not one of the representatives of the "outside party" has the courage to protest against a cardinal and indefensible abuse such as that which we have repeatedly exposed?

THE THEORY OF ARTERIO-CAPILLARY FIBROSIS.

It was inevitable that the new theory of the Pathology of Chronic Bright's Disease should provoke considerable discussion, especially as it went far towards upsetting doctrines that had been pushed with considerable vigour, and, moreover, might admit of further extension.

Abstracts of the paper in which it was originally broached by Sir W. Gull and Dr. Sutton, and that read in reply by Dr. George Johnson, have already appeared in our columns, and some brief comments have been made upon them.

The controversy raised at the Royal Medico-Chirurgical Society is, however, far from concluded, for not only have the original disputants continued their debate but others have been drawn into it. A committee will in due time report, but we may in the interval collect some of the opinions emitted at the public discussion of Dr. Johnson's paper. This is a convenient point at which to begin, apart from its taking up the question where we left it, inasmuch as Dr. Sutton's reply embraces, so to say, the opening of the original case.

It will be seen by reference to our report that at the begining of his paper Dr. Johnson referred to three cases, in which the kidneys were reported by Sir W. Gull and Dr. Sutton to be healthy, the heart hypertrophied, and the vessels thickened, by fibroid changes. Dr. Johnson considered that the hypertrophy of the left ventricle was not due to vascular change, but to vesicular emphysema and to senile degeneration.

Dr. Sutton replied that not only the right ventricle was hypertrophied, but also the left, in many cases of vesicular emphysema; and it was difficult to explain why it should be so in such cases. Clearly this was not due simply to the atrophy or stenosis in the lungs, for these organs were sometimes greatly contracted, the right ventricle dilated and hypertrophied, whilst the left remained healthy. He attributed this hypertrophy to the morbid changes found in the arterio-capillary system. It had been stated that senile degeneration might account for the hypertrophy of the left ventricle; but in using the term senile degeneration no definition was given of the histological changes that had taken place to necessitate cardiac hypertrophy, and the fibroid change described was one form of senile degeneration. It was not asserted that the thickening of the arterioles was always associated with atrophy of the adjacent tissues; but it frequently was.

Dr. Johnson next maintained that the microscopic appearances seen in the vessels and described by them were not *ante-mortem* but *post-mortem* changes.

Dr. Sutton admitted fibroid tissue was seen better in glycerine and water than in salt and spirit and water, but in specimens mounted in salt and water, spirit and water, iodised serum, and albumen and water the outer coat of the vessel had been seen to be thickened by fibroid changes. He reaffirmed that the capillaries had been found thickened in the manner described, and added that later investigations seemed to show that the capillaries were thickened in some cases where the morbid change was little marked in the arterioles.

Dr. Dickinson expressed his belief that the thickening of the tunica adventitia, as observed by Sir W. Gull and Dr. Sutton, was undoubtedly the result of disease, not of *post-mortem* action of any kind. It was seen exceedingly well in vessels which had never been touched with glycerine, but had been hardened in chromic acid and preserved in Canada balsam or some similar material. He found the smaller arteries were greatly thickened, and their channels narrowed. The thickening involved both the muscular and the adventitious coats. The muscular coat was greatly thickened, and at the same time altered in structure, so that the change could not be regarded as a simple hypertrophy. The muscular nuclei became attenuated or extinct, while the striæ, both circular and longitudinal, were exaggerated. The altered muscular coat was almost unaffected by carmine, while the corresponding part of a healthy artery absorbed it abundantly. The thickened muscular coat was generally spotted, sometimes closely, with oil, and often gave evidence of calcareous change, these degenerations causing the liability to rupture present in the circumstances. The outer or adventitious coat also became thickened, sometimes more and sometimes less than the muscular. Sometimes it was increased so as to form the chief bulk of the arterial wall, in other instances the increase in this coat was less conspicuous than that of the muscular. The thickening was not only hyaline, but generally delicately fibroid.

Dr. Bastian said he had frequently met with fibroid changes in the vascular system, and he thought such change more frequent in chronic Bright's disease, and where fibroid change occurred elsewhere. He had also seen hyaline thickening of capillaries occasionally, and once in the capillaries of the spinal cord in a case of locomotor ataxy.

Dr. Broadbent said that in Bright's disease the whole arterial system was in a state of tension. Pyrexia was known to relax the arteries and diminish tension. Passive obstruction from thickening of the arteries by a hyalin-fibroid substance, would, however, prevent them relaxing when pyrexia occurred, though in Bright's disease with this high tension, if pyrexia came on, the tension was lowered. Nitrite of amyl produced the same effect.

Dr. Green agreed with Sir W. Gull and Dr. Sutton that there was no distinct relation between hypertrophy of the heart and change in the kidneys.

Dr. Payne remarked that in Bright's disease abnormal distension of the arterial system was present, and so a great amount of muscular tissue might be a consequence, not a cause.

Dr. Johnson criticised the observations of the several speakers, and supported the proposal to appoint a committee, which was adopted. He also forwarded to the journals a statement that he had intended to say, in reference to Dr. Broadbent's very interesting observation on the effect of nitrite of amyl in reducing the arterial tension in cases of chronic Bright's disease, that, while it is confirmatory of his doctrine that the peripheral resistance is the result of excessive contraction of the hypertrophied muscular arteries, it is quite irreconcilable with the theory that the resistance to the blood flow is caused by degeneration and consequent rigidity of the minute arteries and capillaries. It is obvious that resistance thus originating would be uninfluenced by the peculiar action of the nitrite of amyl upon the muscular arterioles.

Notes on Current Topics.

The Medical Council.

We have reason to believe that the General Medical Council of Education and Registration will meet either on the 12th or 19th of March next. The question of Conjoint Examining Boards, so important to the Profession as well as to the public, will then be brought forward.

A French Retrospect of the Medical Sciences.

Last week appeared the first part of the *Revue des Sciences Médicales en France et à l'Etranger.* It is in the form of one of our quarterlies, and contains 448 pages. It is a full quarterly retrospect, analytical, critical, and bibliographical, edited by Dr. Hayem, and published by M. Masson. Dr. Hayem has secured a number of able coadjutors, who, in their several departments, have worked with a will, so that the *Revue* promises to be the most valuable compendium of Medical progress in the French language.

"Madras Medical Journal."

We are glad to see that the editor of this useful monthly has abandoned his intention of discontinuing it, and announces that for at least six months it will appear as before. We hope in that time our Indian brethren will rally round it and maintain it.

Royal Institution of Great Britain.

The first lecture of the Session before Easter was given on the evening of Friday, Jan. 17, by the treasurer, William Spottiswoode, Esq., LL.D. The subject of discourse was on the Old and New Laboratories of the Royal Institution, and it came most opportunely just as the new laboratories had attained such a state of completion as to be open for the inspection of the audience at the close of the lecture.

The lecturer, after a few graceful compliments expressing how much he was indebted to the honorary secretary (Dr. Bence Jones), proceeded to review the work alone in the laboratories of the Royal Institution from the time of its first establishment, at the close of the last century, by Count Rumford, to the present day.

It seems that at first the so-called laboratory was not much more than a smith's shop, where patent digesters and sundry other culinary utensils were manufactured on highly scientific principles. In later years all this passed away, the smith's forge becoming a chemist's furnace, and in due time the great discoveries of Sir H. Davy and Dr. Young came forth to the world as results of their work in the Royal Institution laboratory.

The lecturer most happily introduced interesting experiments reminding the audience of Dr. Thomas Young's researches on interferences in the undulatory theory of light; showing the way in which its waves are interrupted in passing through a film of wool or a fine grating; and it appeared that Dr. Young proposed this method of examining wools as a means of ascertaining their fineness or coarseness.

Other experiments brought to mind Davy as the discoverer of sodium and potassium, and as the inventor of the safety lamp. Faraday and electro-magnetism came next in order, with some apt experimental reproductions from that great philosopher.

Among men of more recent date, came Dr. Frankland, and his researches on the ethers; and here Dr. Spottiswoode showed how zinc ethyl, by its strong affinity for oxygen, bursts into flame as soon as the tube containing it is broken and contact with air permitted. The effect of condensed air on luminosity was shown, and also the curious fact that while oxygen and hydrogen gases, ignited under ordinary pressure, explode loudly, when they are ignited under a high pressure, brilliant incandescence is the result, with no explosion.

It was not without a struggle that the managers of the Institution had decided on the complete removal of the old laboratories, where Faraday and Davy had done so much; but honoured as the old places were, they were badly lighted and badly aired, and the day had come for them to give way to modern structures and modern improvements.

After speaking of the work of Professor Tyndall, and the liberality of Mr. Fuller, in consequence of the almost blissful evenings that he passed in the theatre of the Royal Institution, Dr. Spottiswoode encouraged his hearers to emulate the generosity of Mr. Fuller, and found professorships for the promotion of scientific research.

The president, Sir H. Holland, occupied the chair, and after the lecture the audience spent a short time in inspecting the spacious new laboratories of the Institution.

Professor Erasmus Wilson will commence a course of six lectures on "Dermatology," at the Royal College of Surgeons of England, on Friday, the 31st instant.

Professor Flower will deliver eighteen lectures on "The Osteology and Dentition of Extinct Mammalia," commencing on the 17th February.

In June Professor Holmes and Dr. Humphry will complete the lectures for the present year—the former by six lectures on the "Surgical Treatment of Aneurism in its Various Forms," in continuation of his course of last year; and the latter by three lectures on the "Varieties in the Muscles of Man."

A Chemical Combination.

THERE has existed for a long time a combination among the manufacturers of iodine, which, with a few brief intervals of disagreement, has been sacredly maintained. During 1872 they resolved to "bull" the price of their staple to an immense extent. Cost what it might, buyers must have iodine, and therefore the manufacturers have had very literally a golden year. The *Chemist and Druggist* observes that, for some inscrutable reason, they have fallen out among themselves, and the consequence was that on the 3rd of January the price of iodine dropped suddenly from 2s. 1d. to 9d.

Adulteration of Cream of Tartar.

A CORRESPONDENT declares in the *American Chemist* that he examined some cream of tartar for a drug broker of that city, and found it to contain *seventy-seven per cent. of alum*. What ought to be done to him?

Amorphous Quinine.

THE *Chemist and Druggist* says that, for some time past, Mr. Broughton, the Government quinologist in India, has been endeavouring to introduce to the hospitals of that empire a cheap substitute for the costly English-made sulphate of quinine. This preparation is simply the alkaloids exactly as they occur in the cinchonas of the Neilgherry plantations. Mr. Broughton has calculated that the Neilgherry plantations might yield about 1,300 lbs. of this article annually, the cost of production hovering between 1s. and 1s. 6d. per ounce, while there is little hope of reducing the cost of quinine below 5s. per ounce. In the Presidency of Madras alone, the consumption of quinine at this time reaches nearly 400 lbs. annually, so that the saving of Mr. Broughton has indicated would be very considerable.

Rivals for the Plush.

THE "leading" Medical journal and the "organ" have frequently engaged in keen rivalry for the honour of chronicling the corn-aches of royalty, which they have been wont to do with oracular pomposity and an assumption of inspired importance, which would make the fortune of a toast-master. As Heaven is to be thanked just now that all "Kings, Princes, and Governors" are in the enjoyment of excellent health, and there is not even a royal cold in the head to work into a paragraph, the "leading" journal is obliged to content itself with thanking Providence that the world is in so beatific a condition. Accordingly, it "is authorised to state that the Empress's health is at present remarkably good."

Bubble and squeak! Did we not know that the "authorised" report is a paragraph to catch a quotation in the daily papers, we should think our contemporary was in its dotage.

Quackery.

A QUACK who calls himself Professor James, was inculpated in the result of a coroner's inquest held last week at Gloucestershire. He had undertaken to treat a woman, who was suffering from heart disease and dropsy, by applying an instrument armed with a bundle of needles to her back and rubbing in an ointment which brought out an immense pustular eruption. The woman died of pulmonary apoplexy, and the jury found that she had been killed by the quack, but, strange to say, did not find him guilty of manslaughter.

This species of quackery is well known in Dublin, having been practised there about three years ago by a German clock dealer, who denominated it the "Exanthematic" system, and who attracted a sufficient number of well-to-do dupes to enable him to set up a sort of sanatorium at Stillorgan, whence he disappeared a couple of years since.

Surgical Society.

AT the meeting of the Surgical Society of Ireland on Friday last, Dr. Henry Kennedy read a paper on "Hemlock in relation to the prevalent Scepticism as to the use of Drugs;" Mr. Swanzy exhibited a drawing of Optic Neuritis; and Mr. Morgan exhibited a dissection of Crispitura Tendinum. Dr. Jacob asked permission to postpone his communication on the accidents peculiar to the operation of flap extraction of cataract, which will therefore be read at the next meeting of the Society on next Friday week.

Sir William Gull on the Case of Napoleon.

SIR W. GULL has thought it consistent with his position to write a letter to the *Times* in reference to some observations made by the *Lancet* and quoted in the *Times*. More surprising still, he has also informed the *Lancet* that he does "not think it proper that he should personally justify himself before the Profession." The opinion of the *Lancet* having been endorsed by ourselves and other journals, may certainly be assumed to be the opinion of the Profession. We would add now that we think it would be far more proper for Sir W. Gull to justify himself before the Profession than before the public. Whether he acted wisely or not in giving a separate opinion on the autopsy of the Emperor is assuredly more a professional than a public question. If an unknown physician had rushed into the *Times* to protest against the comments of the Medical journals as written by persons "imperfectly informed of the circumstances," it would have been regarded as calling for adverse criticism. Our respect for the position of Sir W. Gull must not lead us to adopt another standard for him, and we do not hesitate to say that this last act of his needs far more justification "before the Profession" than his addendum to the report of the autopsy. Anything he had to say should have been to the Profession, and he should have either addressed the Medical journals or maintained a dignified silence.

Prostatic Discharges.

ON January 20th Mr. Henry Lee delivered the second of the Lettsomian Lectures under this title. In referring to the previous lecture, Mr. Lee said he had known secondary syphilis produce a vaginal discharge repeatedly in a married woman, which produced urethritis in the husband on each occasion; he considered that this discharge would have produced primary syphilis in the virgin subject. The lecturer described the experiments of Hunter and others, showing that the vesiculæ seminales are not the receptacles of the semen, and that they are filled with the same fluid after the removal of the testicles as when the glands are present; also observations by himself and others, proving that the testicle may remain healthy although the vas deferens be obliterated, its secretion being absorbed; from this it was inferred that perfect continence does not produce a morbid condition of the gland. The discharge from the prostate, which occurs after defæcation, or at the end of micturition, very rarely contains semen, and does not injure the general health, unless the patient becomes desponding—individuals with light hair, blue eyes, and dilated pupil are particularly liable to this complaint. Mr. Lee prefers astringents to caustic in the local treatment of these affections, as more efficacious, and because he thinks it unnecessary to destroy the mucous membrane; and showed a silver catheter, the stem of which formed a long syringe, used by him for applications to the prostatic urethra. A case was mentioned where this treatment succeeded after cauterisation had failed; the injurious effects of caustics were also commented upon. The injection preferred was composed of from two to four drachms of the Liquor Ferri Perchloridi to eight ounces of water.

London University.

Last week Convocation discussed the propriety of requiring Greek at the matriculation. We are very glad that Greek is not to disappear from the subjects of examination, for we consider that Medical students should all possess a knowledge of the elements of that language.

We fully sympathise with those who desire to entice Medical students to enter the London University, and should be glad for the matriculation and preliminary scientific examinations to be made somewhat less rigourous. But surely enough Greek should be required to render scientific terms comprehensible. There are many other ways of making the University more attractive. The getting up of dates, for instance, might be dispensed with, and the amount of mechanical philosophy demanded might be reduced, while chemistry could be deferred to the preliminary scientific.

Might not something be done, too, in the way of giving optional subjects, somewhat after the manner initiated by the University in their examinations for women?

Sir H. Thompson on the case of Napoleon.

Sir H. Thompson has written a letter to a Medical contemporary to say that the reasons for adopting lithotrity in preference to lithotomy "were distinct and conclusive," and that "the most perfect accord existed between all His Majesty's advisers." This is very satisfactory, and might have been to some extent anticipated, only that rumour has all along asserted that prior to Sir H. Thompson being called in other opinions had been obtained, and that they pointed in a different direction. Whether this be so or not is of little avail. It seems that an ex-Emperor cannot die without the public being interested in the particulars of his illness, and then differences of opinion are sure to crop up. Sir H. Thompson can well afford to wait patiently for the history of the case which he announces is being drawn up by the private physicians of the late Emperor, and which, he tells us, will afford full information on all points of scientific or practical interest to the Profession.

A **Spanish** Medical journal called the *Revista Medica de Chili* is now published in Santiago.

A New Diploma.

All true reformers desire to diminish the number of licensing bodies. Nevertheless, the Obstetrical Society has taken upon itself to issue a diploma to midwives. This is a step in the wrong direction, and should be resented by the Profession. We might as well have the midwives themselves set up a trade union of their own and issue certificates of competency. Free trade in physic, and in diplomas too, has gone far enough, but if we are to have it, let it be openly, and not under cover of a diploma from an unauthorised association of practitioners.

Abortives of the Pustules in Variola.

Dr. Revillod, of Geneva (*L'Union Phar.*, Dec., 1872), says that a mixture he has lately used for preventing scars in small-pox is composed of ten parts of soap, four of glycerine, triturate together, to which is added twenty parts of mercurial ointment. This mass has a consistence such as to be able to be applied to the pustules without causing pain and in an uniform consistence which does not melt. It does not prevent the swelling and produces the desired result, if used at the commencement or before the transformation of the papules into vesicles.

The sudden death is reported of two physicians, Dr. Thomas Thomson, and Dr. Henry Bedwell, of Leamington.

Dr. Livingstone having received the supplies and reinforcements sent forward by Mr. Stanley on the 18th of August, set out for the interior of the country.

Professor Gairdner, in a letter to the *Glasgow Herald*, urges that the owners of houses in which the law is broken by over-crowding should be fined.

The next meeting of the London Pharmaceutical Society will be held on February 5th. The chair will be taken at half-past eight precisely. The following paper will be read:—"Notes on some rare Drugs from Morocco," by Arthur Leared, M.D., F.R.C.P.

Dr. Meymott Tidy has been appointed Analyst for the Whitechapel district for a term of six months. He is to receive for the first hundred cases one guinea for each analysis, for the next fifty cases half a guinea each, and for any number of subsequent cases that occur during the half year six shillings each.

As we stated in our last issue, Dr. Sawyer, Professor of Midwifery in the Royal College of Surgeons, Ireland, has requested the Council to appoint a deputy to deliver a course of lectures on that subject for this session. Accordingly the Council has issued advertisements for such lecturer Dr. Atthill has already announced himself as a candidate.

We noted a fortnight since the advent of three new Medical journals. This week we observe that Messrs. Churchill announce that, on April 1 they will publish, as a monthly, the *Obstetrical Journal of Great Britain and*

Ireland, including midwifery and the diseases of women and infants. It is to be edited by Dr. Aveling, Honorary Secretary to the Obstetrical Society of London, and Physician to the Chelsea Hospital for Women, &c.; and Dr. Wiltshire, Honorary Secretary to the Medical Society of London, Assistant Accoucheur to St. Mary's Hospital.

STUDENTS' COLUMN.

LECTURES ON HUMAN ANATOMY.

By Walter Rivington, M.S., Lond., F.R.C.S., Eng.,

Surgeon to the London Hospital and Lecturer on Anatomy at the London Hospital Medical College.

[Lecture I. appeared as an Original Communication. We place the remainder in the Column for Students.—Ed.]

Lecture II.

The Differential Characters of the True Vertebræ, Cervical, Dorsal, Lumbar—Table of the Differential Characters—Discrepancies of Authors—The Tubercles of the Dorsal Transverse, and Lumbar Articular Processes—Uniformity in the Number of Cervical Vertebræ in the Vertebrates—Three Exceptions—Number of Dorsal and Lumbar Vertebræ in Mammals—Anomalies.

Gentlemen,—Having become acquainted with the common characters of the True Vertebræ, we now proceed to compare the Vertebræ together and to ascertain the points in which they differ individually from each other. In making this comparison we shall dwell only on the more striking characters. It is impossible in Lectures to exhaust any subject, and it would be equally tedious and unnecessary even if it were possible to say everything which is said in systematic treatises. It is the business of the Lecturer to lay down the outlines clearly and sharply, and to leave the finer details to be filled in by the diligence of the student. A Lecture, especially a Lecture on Anatomy, resembles a Picture to be seen from a little distance, which demands bold lines and sharp contrasts rather than delicate shades or elaborate detail. The Lecturer should cull from all quarters and insist on principles; the student, confining his attention to a few text-books, should master each part thoroughly as he proceeds, and complete the picture which the Lecturer has drawn (*a*).

Probably the chief fault which is committed in Lectures is giving too much. Sir Benjamin Brodie, in his "Autobiography," says of Abernethy—"He was an admirable teacher. He kept up our attention so that it never flagged, and that what he had told us could not be forgotten. He did not *tell us so much* as some other lecturers, but what he did he told us well," p. 23. It is quite possible to be a good *Lecturer* and a bad *Teacher*, and even to be both.

The True Vertebræ fall naturally into three groups, corresponding to the three regions in which they are found. The first seven Vertebræ occupying the Neck are called Cervical, the twelve succeeding, placed in the Back, are called Dorsal, and the remaining five, located in the Loins, are called Lumbar Vertebræ. Regarding and comparing these three sets of Vertebræ individually and collectively, we cannot fail to notice that their differential characters are clear and distinct in the centre of each group, but that where these regions join each other the representative characters become shaded down. The first Dorsal approximates in its appearance to the last Cervical Vertebra, and the last Dorsal to the first Lumbar. Hence, if we wish to obtain marked distinctions, we must take a specimen from the middle of each of the three regions; a fourth or fifth Cervical Vertebra, a sixth or seventh Dorsal, and a third or fourth Lumbar.

If we take a fourth or fifth Cervical Vertebra we find that it presents the following features:—

Its *Body* has its long diameter from side to side or transversely; the upper surface is lipped. The anterior surface is prolonged downwards. The lateral lips on the superior surface pass upwards to embrace the lower part of the sides of the vertebra above. They render the upper surface concave from side to side, and their obvious purpose is to prevent the displacement of the vertebræ from each other in the free movements of the neck. Both the anterior and posterior surfaces are flattened, the former slanting forwards, and the latter being nearly perpendicular. The lower surface is slightly convex from side to side, and concave from before backwards. As a whole, the body of a cervical is smaller than that of a dorsal or a lumbar vertebra. Its chief characteristics are its lateral length and its lips.

The *Pedicles* are slender and pass obliquely outwards and backwards.

The *Laminæ* are long, narrow, thin at their lower edge, inclined, and imbricated.

The *Foramen*, enclosed by the *Pedicles* and *Laminæ* or *Arch*, is of large size and triangular in shape. It is larger than that of either the Dorsal or the Lumbar Vertebræ. This circumstance is explained by the facts that the Spinal Cord presents a transverse enlargement in the cervical region, and that the movements of the cervical vertebræ are distinguished for their freedom; hence a large foramen is needed for the protection of the Spinal Cord.

The *Transverse Processes* have four chief peculiarities. They arise by two roots, one from the Body and one from the Arch, they enclose a Hole or Foramen (*a*), they are divided at their extremity so as to present two tubercles, one anterior and one posterior, and they are grooved at their upper surface. For each of these peculiarities there is an object. Their origin by two roots and enclosure of a foramen are to protect a large artery, called the Vertebral Artery, which passes up to the Skull and Brain through the series of foramina presented by the transverse processes of the Cervical Vertebræ. How efficient is the protection thus afforded may be judged from the fact that the Vertebral Arteries remain intact in the fractures and dislocations which occur from violent injuries to the Cervical portion of the Spine. Our Museum contains a specimen recently added by Mr. Hutchinson of complete disruption of all the tissues connecting the fifth and sixth Cervical Vertebræ, and yet the Vertebral Arteries remain unsevered. Their coats are weakened and stretched and seem in part to have given way, but their continuity has not been destroyed anywhere, and they form the only bond of connection between the vertebræ above and below. Wounds of the Vertebral Artery are very rare. The two Tubercles are for the attachment of two sets of muscles, one set being placed in the front and the other at the back of the Neck. The grooves are for the lodgment of the nerves which come off from the spinal cord and pass out to their destination between the two sets of muscles. A second circumstance in connection with the two roots of the transverse process may be mentioned here. The anterior root is the representative of a Rib, springing as it does from the Body of the Vertebra, whilst the posterior, which springs from the point of junction of the Pedicle and Lamina, is the true Transverse Process.

The *Articular Processes* have an oblique direction (*b*), and

---

(*a*) In preparing these Lectures for publication, matter will be added which was not actually given in the theatre, and hence there may appear to be a discrepancy between the principle here laid down and the practice of the Lecturer. It will, however, be very evident that a method suited for a *viva voce* discourse and for impressing the main features of a subject on students commencing anatomy would be too bald and superficial for written discourses. Besides, in an oral lecture, delivered for the purpose of teaching *something*, it is necessary to repeat, to write on a slate, and to ask questions on what has been given, and much less can be delivered within the hour than could be read off in the same period.

(*a*) Sometimes two Holes, the second being much smaller than the other.

(*b*) The *direction* or *aspect* of a surface is found by drawing a line perpendicularly to its centre, the *slope* or *inclination* by drawing a line parallel to the surface.—Ward, "Osteology." First Edition, p. 6.

are hence often termed the Oblique Processes. A line drawn perpendicularly to the centre of the Superior Articular surface passes backwards, upwards, and inwards. A line drawn perpendicularly to the centre of the Inferior Articular surface passes forwards, downwards, and outwards.

The *Spinous Process* is short, inclined more or less downwards, and bifid at the extremity as if made of two lateral halves which had partially coalesced and then divaricated. The two tubercles at the extremity attach the tendons of the muscles on each side of the spine. Of the Notches, the Superior are deep and narrow, the Inferior shallow and broad.

If we now take the sixth or seventh Dorsal Vertebra we find that its features are markedly distinct. The *Body* is heart-shaped; it is hollowed behind, is prolonged forwards in front, and is wider considerably behind than before. It is distinguished by the presence of four small articular surfaces for the reception of the Ribs. These articular surfaces, or *facets* as they are generally termed, are characteristic of a Dorsal Vertebra. You do not find them either on the Cervical or the Lumbar Vertebræ. They are placed on the upper and lower margins of the Vertebra at the posterior part of its lateral aspect, are covered by cartilage in the recent state, and form, with the corresponding facets on adjacent vertebræ and the uniting intervertebral substance, complete cavities for the Heads of the Ribs. The upper and lower surfaces of the body are flat, the anterior convex, and the posterior concave from side to side. It is deeper behind than in front.

The *Pedicles* pass directly backwards from the upper part of the body.

The *Superior Notches* are shallow,

The *Inferior* deep and broad;

The *Laminæ*, which are short, deep, and thick, overlap each other like tiles.

The *Arches* enclose a small rounded *Foramen*, the smallest foramen of the three.

The *Transverse Processes* pass obliquely outwards and backwards. They are long, thick, and strong and terminate in a clubbed or triply tubercular extremity, which presents anteriorly a concave articular facet for the reception of the smooth facet on the *Tubercle* of the *Rib*.

The *Articular Processes* are nearly vertical in position. The *Superior* articular surfaces are flat, and are directed backwards, a little outwards, and upwards. The *Inferior* surfaces, also flat, are directed forwards, a little inwards, and downwards.

The *Spinous Process* is very long, triangular, or "bayonet-shaped," passes obliquely downwards, is tubercular at its extremity in some of the Dorsal Vertebræ, and overlaps the spinous process immediately below.

If we now take the third Lumbar Vertebra we find that it has been made in a rougher, and, so to speak, a coarser, mould than either the Dorsal or the Cervical Vertebra.

All its parts are more marked, it is the largest and strongest of the three, and obviously adapted to carry a heavier burden.

The *Body* is large, with its long diameter from side to side, a deep constriction in the centre of its outer surface, and very prominent margins. It is rather thicker in front than behind.

The *Pedicles* are strong, and pass directly backwards from the body.

The *Notches* are large.

The *Laminæ* are short, broad, and strong.

The *Arch* encloses a large triangular foramen, larger than that in the Dorsal Vertebra, but smaller than that in the Cervical.

The *Transverse Process* is long, slender, with thin margins, and directed transversely outwards, and a little upwards.

The *Articular Processes* are vertical, and "curved so as to lie in the arc of a circle" (Quain's Anatomy). The surfaces of the Superior Processes are concave and directed backwards and inwards, while those of the Inferior are convex and directed outwards and a little forwards. Moreover, the Superior Processes are placed more widely apart, so as to embrace the Inferior—one of the many securities against dislocations.

The *Spinous Process* is thick, broad, quadrilateral, rough, and prominent along its posterior edge.

The peculiarities of the Dorsal Vertebræ have reference to the limited movements of the spine in the dorsal region, to the attachment of the ribs, and to the formation of the thoracic cavity. The peculiarities of the Lumbar Vertebræ have reference chiefly to freedom of motion, and to the increasing weight which they have to sustain.

Let me place the chief features of the three sets of Vertebræ in a tabular form for the purpose of comparison, contrast, and facility of reference:—

		CERVICAL.	DORSAL.	LUMBAR.
Body		Long diameter from side to side, lipped above, anterior surface prolonged downwards.	Heart-shaped, wide behind, narrow in front, facets for ribs, long diameter, transverse.	Large, rough, long diameter, transverse, deeply constricted, prominent margins.
Arch	Pedicles	Obliquely outwards.	Backwards.	Strong, backwards.
	Laminæ	Long, narrow, imbricated, thin at lower edge.	Short, deep, thick, and imbricated.	Short, deep, and strong.
Foramen		Large, triangular in size, No 1.	Small, circular, No. 3.	Triangular, No. 2.
Transverse Process		Two roots, bifid, two tubercles, a groove and a foramen.	Obliquely outwards and backwards, thick and strong, 3 tubercles and a facet for the rib.	Long, slender, transversely outwards. Tubercles above have joined the articular processes.
Articular Process (a)	Superior	Inclined and looking backwards, upwards, and inwards. BU.	Nearly vertical, flat, backwards, outwards, upwards. BO.	Concave embrace, lower, backwards and inwards. BI.
	Inferior	Downwards, forwards, outwards.	Nearly vertical, forwards, inwards, downwards.	Convex, outwards, and a little forwards
Spinous Process ..		Short, bifid, nearly horizontal.	Long, triangular, obliquely downwards, overlapping, tubercular.	Thick, broad, quadrilateral, and rough.
Notches	Superior	Deep and narrow	Shallow.	Shallow.
	Inferior	Shallow and broad.	Deep and large.	Large.

(To be continued.)

A STORY OF WATERLOO.

(Compiled by C. A. GORDON, M.D., C.B., &c., &c.)

ALTHOUGH the greatest of England's victories is now in a measure out of date, having been eclipsed by recent events on the Continent, there is at least one respect in which a reference to it may have an interest to our military brethren. So much attention has of late years been given to the physical constitution of armies, to means for supplying them with food, and in regard to necessary provision for sick and wounded, that some at least may be interested to learn what was then the case in these several respects.

Unfortunately, Medical Blue-books were not then in fashion, neither, so far as we are aware, have any reports on this great battle appeared in print from the pen of any Medical officer present on the occasion. Perhaps some of those who still live may favour us with a few remarks on the sanitary arrangements connected with the battle, but in the meantime we take the very interesting "Story of the Battle," by the Rev. G. R. Gleig, M.A., Chaplain-General, and make such extracts as appear desirable.

The troops at the disposal of the Duke of Wellington are described as having been raw, and dispirited; those of his opponent as the best appointed and best disciplined of any that even Napoleon had ever commanded.

That the means of removing the wounded off the field were very limited we have many proofs. On the night of 16th June, after the repulse of the Prussians at Ligny, it is on record that it was impossible to collect the wounded and carry them to places of shelter; nearly all were therefore left where they lay, and very piteous were the groans and cries of many of them throughout the succeeding night. It would appear, however, that carts and conveyances for the purpose were on the following day sent out from Brussels, for on the 17th many of the wounded were by such means conveyed to that capital.

(a) The main direction of the Upper Articular Processes in each region may be remembered by the use of the initial letters, BU., BO. (bubo is a word not unfamiliar to the student), BI. Of course, the Inferior Articular Processes will have directions exactly the reverse of the Superior.

The available means of transport among the Prussians must have been very defective, for Blucher, who was severely crushed by a fall under his horse, had to be laid across the back of a trooper, and thus borne from the field. During the terrific struggle within the enclosure of Hougomont, the absence of men or means to remove the wounded was the occasion of a remarkable and striking incident. At the moment when flames burst out in the adjoining church, in which a number of the wounded had been deposited, Sergeant Graham, who was bearing himself with great bravery upon the banquette, asked permission to retire for a moment. Colonel Macdonell granted it, but asked why was it solicited at such a time—only, said the sergeant, that he might search for his brother, who was among the wounded in the burning building. He soon found him, carried him in his arms to a friendly ditch, where he laid him, then resumed his own place in the fight, where his gallantry was again conspicuous.

Picton, while leading his division in the charge, was killed by a musket bullet through the head, and was carried to the rear by his own men. Shaw, the life guardsman, however, exhausted by wounds received in hand to hand fight, remained with thousands of other wounded men upon the field all night, and in the morning his dead body was discovered in the general search then made.

Colonel Ponsonby, severely wounded, was left upon the field for want of means of removal. For a time he was in the hands of the French, after, indeed, a lancer had run him through the chest, as he lay helpless on the ground, uttering as he did so, the exclamation, "Tu n'est pas mort, coquin." Another Frenchman, however, more humane, placed a knapsack under his head, gave him his brandy flask to drink from, and then left him to pass the night of the 18th on the field.

After the battle of Quatre Bras, on the 16th of June, it is evident that surgeons were not present on the field, at least in any considerable number. When the Duke of Brunswick was here struck down fatally wounded, he was carried to the rear, and laid down in a field, while search was made for a surgeon. At last a staff surgeon came to him, but it was too late.

Food seems to have been abundant on the French side, but on that of the English, supplies for the troops and forage for horses were alike deficient in the interval between the first fights between the opposing armies on the 16th, and the great struggle on the 18th. In regard to the latter, these defects were perhaps not to be wondered at under the circumstances, as the movement of the allies was for the time being retrograde.

On the night succeeding the great victory, the Anglo-Belgian army lay on its arms in the field it had won. They stood much in want of provisions, but no provisions came, nor were the means at hand to send them forward. The British soldiers were very hungry, but they could not bring themselves to eat the viands found on the heights of Belle Alliance, where the French had bivouacked the previous night. They had found there raw meat of every description in abundance, beef, pork, and mutton; the very hides in some instances left upon the morsels, and these indifferently bled. Faint as they were, they flung such food away in disgust.

Both Napoleon and Wellington showed solicitude in regard to the sick and wounded. The former issued special directions on this subject after the battles of Quatre Bras and Ligny. He rode over the field on both occasions, gave directions that the wounded should be taken care of, and spoke to the different regiments as he passed them. During the 17th and following night arrangements were being made on the British side for expected wounded on the succeeding day—apartments fitted up in every house, not only in the village of Waterloo, but along the entire rear of the position; and we learn that in the course of the 18th wounded and fugitives came crowding back.

A very complete and touching account is given of what would now be called the ambulances after the battle. As the Duke of Wellington returned to the small village of Waterloo, and entered the house selected as his headquarters, he found every apartment filled with wounded, and, to repeat the words of Mr. Gleig, their kind and indefatigable Medical attendants. And the Duke's heart sank within him as he looked around. Dr. Hume passed to and fro, bringing aid where it was wanted, or directing others to perform offices deputed to them. Almost all the houses there and further in the rear had been converted into temporary hospitals. Straw covered the earthen floors, but wholesome sheets were spread over it. The wounded lay with scarcely an interval between them; surgeons and their assistants gave to each intern such attention as they could bestow. There was no rest, no sleep all that summer's night, next day, nor for many days afterwards to those ministers of health! The marvel is how they succeeded to any extent in paying heed to the incessant and multitudinous demands upon their skill. Everywhere around, in the capital and the country, every door was opened to receive the wounded. Delicate women waited upon them and dressed their hurts. Ladies of rank and men of property gave up their rooms, or sent to the hospitals bedding, wine, brandy, linen, vegetables, and fruit. Subscriptions were set on foot to create a Waterloo fund for the supply of relief to the wounded, their families, and to increase the allowance to the disabled and to the widows of the dead. Numbers of Medical men, at their own cost and still greater personal inconvenience, hastened from London and elsewhere to lend assistance.

We learn that after the battle the wounded and their attendants *streamed* into Brussels, the latter even in greater numbers than the former. Such of the men injured as were unable to reach the capital crept into the wood of Soignes, and there sat down, many of them to rise no more. Waggons and carts had gone out for them and brought back numbers. It does not appear, however, whether those waggons were part of the regular transport of the army, whether they were voluntarily supplied or "requisitioned."

Fatigue parties went out in all directions, the melancholy spring waggons were busy in the prosecution of their melancholy work; feeble movements of limbs or attempts to rise to a sitting posture pointed out where the wounded still lay thick among the dead.

Literature.

ENGLISH MIDWIVES THEIR HISTORY AND PROSPECTS. (*a*)

We are much indebted to Dr. Aveling for his contribution to our stock of knowledge on the above subject. The information his book gives, will do much towards explaining the present relations of accoucheurs and midwives to the practice of midwifery in this country.

The book gives a sketch of the history of midwives, from the 16th century to the present time. Chapter I is occupied with the 16th; chapters II. III. IV. and V. with the 17th; chapters VI. VII. VIII. and IX. treat of the 18th; and chapter X. deals with the present century, while chapter XI. is devoted to the consideration of how best to realize the requirements of the age.

(*a*) "English Midwives, their History and Prospects." By J. H. Aveling, M.D.

Dr. Aveling first shows us the position of midwives in the 16th century, how that they were licensed by the bishops in consequence of having frequently to baptise the child; and that they were only prohibited from performing this duty about the commencement of the 17th century, but that they still continued to be licensed by the bishops, until the middle of the 18th century. Mrs. Cellier, however, mentions that between 1642 and 1662, the midwives were licensed at Chirurgeon's Hall, but not till they had passed three examinations before six skilful midwives, and as many chirurgeons expert in the art of midwifery. It does not appear on what grounds those examinations were discontinued. During both the 16th and 17th centuries, the practice seems to have been almost entirely in the hands of women. In the beginning of the 17th century, Peter Chamberlain began to practise midwifery, and it was from him that the first proposal came "for the instruction of civil government of midwives." Unfortunately, no action on the matter was taken. "Had this proposal been carried out at that time," says Dr. Aveling, "England would have been in the van of the movement which has been going on in Europe since Peter Chamberlain's days, instead of in the rear; our midwives would have been for more than two centuries properly instructed, and controlled, and we should have been saved the humiliation of being pointed at by our continental neighbours, as a nation which does not care so much for the lives of its mothers, as to induce it to secure for them sufficient help in their times of jeopardy." In spite, however, of the disadvantage of the time, many of these midwives were women of considerable skill and ability. Dr. Aveling gives us quite a list of the most notable women of the time, the greater number being royal midwives. Among those mentioned at this period, Mrs. Jane Sharp was the first to publish a work on the art of midwifery. Mrs. Cellier, also gained for herself considerable notoriety from her political intrigues. "A scheme for the foundation of a Royal hospital, and the maintenance of a corporation of skilful midwives" was originated by her, but was not found practicable.

During this century, the practice of midwifery made immense advances, owing chiefly to the labours of Drs. Chamberlain, Harvey, &c., who to their credit, be it said, made many endeavours to improve the education of midwives of their time. "Up to this time," Dr. Aveling tells us, "the man-midwife was not employed in ordinary cases, his assistance being only sought when instrumental interference became necessary," for which, however, they do not appear to have been very grateful.

Dr. Aveling gives us an interesting account of the struggles between the man-midwife, and the midwife. The midwives strove hard to hold their own against the encroachments of the man-midwife, and against the use of the forceps, and which gave men their most telling advantage. Mrs. Stone, the second lady writer on midwifery, Mrs. Kennon, and Mrs. Nihell, were among the most prominent opponents of their introduction. Mrs. Stephen is only an opponent of men-midwives. She seems not to have been satisfied with the instruction afforded to women, for Dr. Aveling quotes from her, "I intend to continue my lectures as usual to women entering upon the practice of midwifery, until the men who teach that profession, render them unnecessary by giving their female pupils as extensive instructions as they give the males."

Dr. Aveling demurs to this charge of Mrs. Stephens, which is also repeated by others, and thinks that the writings of the men-midwives of the time, show that their most earnest desire was, "to instruct and improve the midwives." "The men constantly declared that they had no wish to injure in any way their sister practitioners."

Dr. Mawbray earnestly laboured as a teacher of midwifery, and put forward a list of the qualifications and knowledge which he considered a midwife should possess. Sir Richard Manningham, in 1739, established a lying-in ward in St. James's, Westminster, where midwives might receive proper instruction.

Dr. Aveling says, "It is remarkable, considering the number of proposals for the instruction and government of midwives, which were made during this century, that no effective step should have been taken." "When the Church undertook the control of Medical affairs, it gave licences alike to physicians, surgeons, apothecaries, and midwives, but when the faculty took these matters into their own hands, midwives were ignored." "In reviewing the progress of obstetrics during the 18th century, this appears to have been the only retrograde step."

Coming to the present century, Dr. Aveling notices the effort made by the Society of Apothecaries in 1813, to persuade parliament to pass enactments for the examination and control of midwives. He also alludes to the Obstetrical College, which has "provided the public with excellent midwives, capable of attending cases of natural labour, and recognising difficulties requiring more skilful assistance," and he speaks highly of a scheme elaborated by Miss Nightingale for the instruction of midwives. The regulations also of the examinations of midwives, held by the Obstetrical Society are given in full. The diploma granted by this Society gives no legal standing, but Dr. Aveling tells us, that "the General Medical Council has passed a resolution, which if carried out, will remedy the defects of the Obstetrical Society's scheme, by providing for the education and registration of midwives." Dr. Aveling shows that, in the villages, a large proportion of the population, varying from 30 to 90 per cent. is attended by midwives, and the proportion is almost as large among the labouring population in manufacturing towns. In the east of London, from 30 to 50 per cent. are attended by midwives; in the west, scarcely 2 per cent. Taking the population of England and Wales to be 23,000,000, according to the calculation adopted in Germany and France, there should be 11,500 midwives in this country.

POPULATION AND FOOD (*a*).

The work by Mr. W. R. Greg is a collection of eight essays on various knotty problems of speculative philosophy. The author is well known in the literary world, and the book is worth perusing by Medical men, although it is perhaps rather literary than scientific in some parts. The second essay, denominated "Malthus Notwithstanding," speaks of the check which was sustained by the writers who, like Southey and Coleridge, R. Owen, Fourier, and St. Simon, dreamed of the perfectibility of the race, by Malthus's work on the "Population Theory at the end of Last Century." "Malthus (says Mr. Greg) demonstrated, or was held to have demonstrated, that a condition of universal comfort and plenty as that shadowed forth could never be reached on earth, inasmuch as there was a constant and irremediable pressure of population on the means of subsistence; that it was in the nature, in the essence of human beings, to increase in a more rapid ratio than food; that, as long as and whenever population did increase faster than its sustenance, the great mass of mankind must be in a state of wretchedness; and that this incurable tendency could only be counteracted by what were merely other forms of wretchedness—viz., profligacy, excessive and premature mortality, or abstinence from marriage, or, as he phrased it, by vice, misery, or moral restraint."

In an article "On Population," which Mr. Malthus

(*a*) "Population and Food." A Review by C. R. Drysdale, M.D., M.R.C.P.L., F.R.C.S.E., Physician to the North London Hospital for Consumption.

"Enigmas of Life." By W. R. Greg. London: Trübner. 1872. Pp. 308.

"Principles of Biology." By Herbert Spencer. Vol. ii.

"Gynæcological Society's Transactions." Paper by Dr. Storer, of Boston, February 20th, 1872.

"Principles of Political Economy." By J. S. Mill. Book ii, Chap. iii.

contributed to the eighth edition of the "Encyclopædia Britannica," he lays it down as indisputable and obvious, that population, if unchecked, tends to increase in a geometrical ratio, and that food, the produce of the soil, can only at the outside increase in a geometrical ratio. That the inhabitants of a given country or area will, as is seen, actually double their numbers in twenty-five years, and might easily double in a much shorter time; whereas, even if we concede that in the same twenty-five years the produce of the soil in the same given country or area may be doubled likewise, it is certain that in the *next* twenty-five years, while the population would *tend* to double again or quadruple its original numbers, the soil could at most only add an equal increment to that of the preceding period.

"Malthus's doctrine (says Mr. Greg) has been accepted as undeniable by nearly every writer of repute on economical subjects, and by none more unreservedly than by the latest, and in some respects the ablest of all, J. S. Mill. None of the many authors who have questioned or assailed it, such as Ingram, Alesior, Sadler, Doubleday, or Quetelet, have been able to shake in any material degree its hold upon the public mind . . . Some years ago I hoped to be able to show, in opposition to the received doctrine, that, however irrefutable was Malthus's logic, his premises were imperfect, and his conclusions in consequence unsound. It is with some sadness that I am compelled to admit that further investigation and deeper thought have shaken this confidence."

Mr. Greg, however, has some misgivings as to the truth of Malthus's theory—firstly, because, even in some parts of Mexico and the United States, the actual doubling never seems to be much faster than twenty-five years; whilst the theoretical powers of the species would suggest a possible doubling in less than ten years. "In the United States and Lower Canada, which come next, it is calculated that when the large immigration is substracted, the period of doubling by natural increase is twenty-five years. But this falls far short of the possible rate of theoretical increase, since, adopting data which are actually reached and indeed extended in some instances, the population of a country can double itself in less than ten years. Again, the ordinary size of families in England and Wales, judging by a comparison of the yearly marriages with the yearly births, is now about 4·15 children, and we may fairly assume that with us no artificial means, of abstinence or otherwise, are employed to prevent each marriage yielding its natural number of offspring. . . . We cannot, with any accuracy, ascertain the number of children born to a marriage in America, as statistics there are complicated by immigration, migration, extension, and other causes; but I believe no one would place the average higher than six. But the possible number of children to a marriage—the *natural* unchecked number under the best conditions is far beyond this—is certainly four-fold. The child-bearing ages of women extend over nearly 30 years—certainly over 25, or from 16 to 40 inclusive, on a moderate estimate. Twenty-five children to each marriage is, therefore, no impossibility; in favourable conditions we should say no unlikely occurrence."

On page 69, Mr. Greg observes that "nowhere in the United States, one would suppose, can pressure of population on means of subsistence be alleged as the true acting cause of non-increase of numbers or failing fecundity; yet, it is asserted confidently (and there seems every reason to believe with accuracy), that the native-born citizens of some of the New England States cannot—at all events *do* not—keep up their numbers." Dr. Storer, of Boston, is quoted as an authority on this point, and as will be seen in the MEDICAL PRESS AND CIRCULAR, of Nov. 20, 1872, Supplement, that gentleman, in a paper communicated to the Gynæcological Society of Boston, February 20th, 1872, maintains that the inhabitants of some of the States imitate the Parisians, and other inhabitants of France, in voluntarily limiting their families. "In this connection (says Dr. Storer) I would for a moment refer to a subject which seems entirely to have escaped the notice of the Medical writer; and yet it is one which most often forces itself upon the mind of the physician, not merely as a prominent ground for variations in the tables relating to population, but also as being a not inconsiderable cause of uterine disease. I allude to the means so extensively used to prevent impregnation. Although there exists a large number of individuals whose conscientious scruples would prevent them from deliberately producing an abortion, very many of them seem to think it perfectly safe and right to use all practicable means to avoid conception. To such an extent is this feeling carried that it is a very common occurrence for the physicians to be told that children need not be conceived, and by such persons they are not conceived; frequently to these individuals no children are ever born."

This passage from Dr. Storer may explain to Mr. Greg that there is nothing very mysterious in the population check which at present acts so strongly in some parts of the United States, and probably in Boston and its neighbourhood. It is the fear of poverty which keeps that population so nearly stationary, not any occult influence, such as Doubleday or Herbert Spencer, are wont to expatiate upon. We suspect that, as Mr. Greg says himself, in page 69, "the repellent character of Malthus's conclusion has been usually regarded as in itself a ground for suspecting its truth . . . There are certain truths which the general sense of mankind has adopted and clings to as undeniable, partly from instinctive conviction, partly from overpowering proof, partly from religious teaching,—such as the wisdom, power, and ultimate essential universal goodness of God. It is right and wise to doubt *provisionally*—not of course to deny—any doctrine which contradicts or seems to contradict these truths, and which has been arrived at by steps of logic." This is the sort of argument which satisfies Mr. W. R. Greg, as he explains in Chapter I. at considerable length; but is one which may be said to be moribund now among intelligent persons, and held in contempt by modern physiologists, or other scientific inquirers, and, as Mr. Alexander Bain has well said, "Science is the Regenerator of Mankind."

Mr. Herbert Spencer is not affected with these theological disabilities for being a thinker, as we fear we must say of Mr. Greg, notwithstanding the excellent service the latter writer has done in his work on the "Creed of Christendom," and it is, therefore, curious to study Mr. Spencer's way of getting out of the Malthusian difficulty. If we turn to his "Principles of Biology," vol. ij., chap. 13, we find that Mr. Spencer holds that diminished fecundity and reduction in the rate of increase *must* physiologically ensue from mental action and advance of civilisation. "It is manifest that in the end pressure of population and its accompanying evils will disappear, and will leave a state of things requiring from each individual no more than a normal and pleasurable activity. Cessation in the decrease of fertility implies cessation in the development of the nervous system, and this implies a nervous system that has become equal to all that is demanded of it, has not to do more than is natural to it. In the end, therefore, the obtainment of subsistence and the discharge of all the parental and social duties will require just that kind and amount of action needful to health and happiness . . . The excess of fertility has rendered the process of civilisation inevitable, and the process of civilisation must inevitably diminish fertility, and at last destroy excess. From the beginning, pressure of population has been the proximate cause of progress . . . And after having caused, as it ultimately must, the due peopling of the globe, and the raising of all its habitable parts into the highest state of culture, after having brought all processes for the satisfaction of human wants to perfection, after having, at the same time, developed the intellect into complete competency for its work and the feelings into complete fitness for social life, the pressure of population as it gradually finishes its work, must gradually bring itself to an end."

Correspondence.

ETHER AS AN ANÆSTHETIC IN OPHTHALMIC CASES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The unfavourable experience of the house-surgeon of the Royal London Ophthalmic Hospital, as expressed in the *British Medical Journal* last week, respecting the use of ether in ophthalmic cases, exactly coincides with that of Mr. Wilson, of Dublin, as detailed by him at the Surgical Society of Ireland a month ago. I think that the statements of these two gentlemen, being so completely coincident, go far to prove that ether *as administered by them* is an anæsthetic unsuitable for the performance of eye-operations. They do not, however, afford the least evidence that that anæsthetic given in a different manner produces the results which they have experienced, or is open to any objection in ophthalmic practice; and my observation of its use in a considerable number of ophthalmic operations of all degrees of gravity, enables me to say that the unpleasant symptoms to which these gentlemen have referred are in no respect the fault of the anæsthetic, but are dependent entirely on the method of administration. I have not seen ether administered by the towel and sponge, but I am not at all surprised to learn that its use in that way—mixed with a large quantity of air—has given rise to violent delirium and vomiting. I am satisfied that those *désagremens* are the result of the dilution of the vapour with air, and that they will almost never occur if the ether be given by the inhaler recently invented by Dr. Morgan, of Dublin. The principle of this instrument is to exclude the air as much as is possible, and to cause the patient to rebreathe the vapour until perfect anæsthesia is produced. I have, within a few months, performed forty-two operations on the eye with the aid of ether given by Dr. Morgan's inhaler. In one case only out of the whole was there vomiting during the operation, the patient having, in disobedience to orders, taken a full meal immediately previously. In no case was there sickness afterwards. In several cases there was muttering delirium, but in only one was there violent excitement, which we were unable to understand until we discovered that the elastic diaphragm of the inhaler was torn, and that a quantity of air was being inhaled with the ether. In nine-tenths of the cases the anæsthesia was rapid, calm, complete, and undisturbed, and the recovery immediate and unchecked. As the mouthpiece of the inhaler fits closely to the face, a very small quantity of ether vapour can reach the atmosphere of the room, and the conflagration which "the house-surgeon" anticipated is impossible.

This report of the administration of ether may meet with some scepticism in consequence of its roseate colouring; but I believe that any of your readers, who will make trial of the administration with the inhaler to which I refer, and with a good specimen of the ether, will be satisfied that I am not chargeable with exaggeration. Arguments against he use of that agent are meaningless, unless it be shown that it is given in the right way.

I am, &c.,
ARCHIBALD H. JACOB, M.D., F.R.C.S.
Dublin Infirmary for Diseases of the Eye and Ear.

A NEW CHARITY!!

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—May I venture a suggestion as to a new charity? My sympathies and those of others have often been painfully excited by the sufferings of the deserving poor, who having a matter against a neighbour or burning under the sense of some injustice desire to appeal to that law which is so well known to be open equally to the rich and the poor, but cannot obtain justice through lack of means. This, then, is my proposition:—To have an established hospital duly officered, with in- and out-patient departments, the beds being occupied by those who, suffering under long and tedious litigation, would be, by mental worry, prevented from pursuing with advantage any ordinary occupation; these unfortunates would be skilfully attended and their cases, if possible, brought to a successful issue by our most eminent barristers, who, doubtless, are but waiting for the chance to imitate the members of the sister profession of medicine, and would vie with each other in the endeavour to obtain an appointment on this staff, where they might have the opportunity of bestowing gratuitously the results of their labour and skill, hoping thereby to derive a satisfaction which would probably owe its chief charm to its novelty. The out-patient department for minor cases of litigation, with special arrangements for wills, loans, &c., would be also a most valuable school for the junior members of the Profession, who would thus, while acquiring a vast experience, be qualifying themselves for the higher appointments when their seniors had gone to receive the reward which they, in company with the Medical Profession, would in time accustom themselves to look for in some other world than this.

Should this suggestion find favour in your eyes and those of your readers, may I crave your help to establish the charity, so that before long Medical attendance and medicine may not be the only things in this world which can be obtained absolutely for nothing?

I am, Sir,
Your obedient servant,
Jan. 22, 1873. A. W.

THE ADMINISTRATION OF IRISH LUNATIC ASYLUMS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I should prefer leaving to others the controversy and correspondence on this subject. I have received through the post a reprint of various articles which appeared in the MEDICAL PRESS AND CIRCULAR; I have also accidentally seen a reprint of a letter by a Visiting Physician, addressed to a local paper, in consequence of its having quoted portions of your articles; and I have read in your last issue Dr. Maconchy's letter, which, like the former, questions the accuracy of your statements, and gladly testifies to the harmony existing between the Medical officers in their respective asylums. It is with very great satisfaction that I can personally state that similar friendly relations exist between me and my colleague, who is now my brother-in-law, and with whom I enjoyed professional intimacy before his appointment to the Maryborough Asylum. But all these cases are but negative; and I cannot allow it to be represented that all is smooth in asylums generally without through you calling attention to some facts.

No doubt your articles are to be understood as dealing with the system as a whole, and I am aware by your former articles, in years gone by, that you are in possession of details which justify the putting of your arguments in very strong language.

Now I distinctly state that, though there are some happy exceptions, the feeling—large, if not general—is one of impatience by the resident towards the visiting officers. I have seen much of it in the Maryborough Asylum, where it had an undesirable notoriety; and since my own appointment, several years ago, I experienced it on the occasion of my visiting on other than the usual day a case which I considered required daily attention. I was informed with much warmth that such visits were not contemplated, were outside my duty, and were offensive to a resident Medical officer.

I am aware of the expounding of the rules to junior by senior resident Medical superintendents, pointing out what was and was not the duty of the visiting physician. In this way it even happened that certain changes in the rules first came to my knowledge, which, by the way, are successively and insidiously, slowly and surely shelving the visiting physicians. Were such changes introduced like a Parliamentary Bill, there would be a fair opportunity for honest protection of interests, instead of our first knowledge of a real but covered injury being in the appearance of new orders.

Several visiting physicians have considered it necessary to seriously consider these matters in self-defence, yet they are not aggressors. Some have been careless for many years, and some have been informed that they do more than their duty, when they have thought otherwise.

It will be in the recollection of most of your readers that the history of the office of resident Medical superintendent is that under the original Privy Council rules framed by the late able Lord St. Leonard's, each asylum was governed by a layman called the Manager. In due time it was very properly considered desirable that the manager should be a physician, his duties, however, continuing lay and fiscal. It has been but very recently that the title "Manager" was changed to that of resident Medical superintendent, when commenced the transfer of Medical duties from the visiting to the resident officer—a change at first strictly limited to the treatment of mental disease, but now less openly and honestly, but not less surely, including the treatment of bodily disease.

In your editorial note you quote from the Privy Council rules as follows: "The consulting physician is on his arrival to communicate with the Medical superintendent, in company with whom he shall visit, besides patients labouring under bodily disease, *whose course of treatment he shall direct*, and in seclusion," &c. Now, Sir, the rule you quote has been pruned up in a recent issue (1870), and the words "whose course of treatment he shall direct," have been expunged. Again, in a former rule directing the visiting physician to "at least once a fortnight examine into the mental condition of every patient in the asylum," in the recent rules this has been changed as follows, "He shall once at least in each fortnight examine, with the resident Medical superintendent, into the mental condition of every patient in the asylum *who is under special Medical treatment*." Many similar changes have taken place from time to time.

Now, Sir, I distinctly state that there should be none but the most harmonious and cordial co-operation between the Medical officers. Rivalry or jealousy is abnormal, unsound, and a scandal; it exists, nevertheless, and the visiting physicians are not the aggressors, they are on the defensive for their rights and their general professional endowment of £2,700 annually, which it is sought to alienate with the connivance of some members of our Profession, whose salaries would not be improved by the spoliation, and whose duties and *responsibilities* would be increased by the removal of visiting physicians.

As to visiting physicians being a check from without on the residents, and a guarantee to the public, against abuse, such a feeling undoubtedly does exist amongst the governors, and that feeling has had its origin in the insidious changes in the regulations which they could not overlook.

It appears to me that the resident Medical superintendents have ample use fully to occupy their time, having completed the daily consideration, direction and treatment of the insane under their care, and having disposed of the very considerable amount of "management" and fiscal duty which was formerly alone considered enough to employ the time of a well-paid lay manager; and having devoted any possible leisure to the study of psychological literature, and the noting for the benefit of others the experience their opportunities afford, those who now think otherwise may see that, without any great sacrifice of dignity, they can leave to the visiting physicians the comparatively small amount of general Medical duty which secures them salaries, which, in the aggregate, cannot be spared by our Profession, and which duties require the aid of experience and daily practice which we must humbly admit is too often insufficient to combat disease, and which physicians and surgeons retired from general to special practice are the less able to afford.

In conclusion I must refer to an attempt to establish in Ireland a so-called Psychological Society, which the resident physicians only were invited to join to the exclusion of the visiting physicians and physicians of private asylums. I will hope that the omission was accidental, but though I am aware that attention was called to the circumstance it has never been corrected. Was the object sinister? I understand the association has collapsed.

Very faithfully,
DAVID JACOB,
Surgeon to Queen's County Infirmary, Visiting Physician Maryborough District Asylum, Proprietor of the Midland Retreat.
17th January, 1873.

[It is not our object, in pointing out the narrowing tendency of the Privy Council rules, to set class against class, or to excite a feeling of jealousy or ill-will between visiting physicians and resident Medical superintendents. We leave that employment to those who have been gradually tightening the bit until both governors and visiting officers have become restive. There would not be, nor ever was under the old system, any clashing between the extern and intern Medical officers, but the former class are sharp enough to see that the policy of gradually transferring their duties to the resident, and making their visits a mere formality, can only have one object and ending—their disestablishment and disendowment. We cannot allow that little plot to be worked out without suspicion or protest, and we warn visiting physicians that the next step from mere formal duties is no duties at all.

Our chief concern, however, is that the former system of supervision and watchfulness over the management of asylums shall be maintained. We don't wish to see the thousands of poor lunatics in Ireland consigned to establishments into which no vigilant eye is allowed to get a glimpse, and we believe it will be admitted, with the remembrance on our minds of the condition of the Limerick Asylum and the murder of the lunatic Danford, and the more distant recollection of the *exposé* which began at Maryboro' and ended at Castlebar, that, without doing an injustice to resident Medical superintendents as a body we have cause for our apprehensions. The brief interval since we last wrote has furnished us with an illustration, for we learn that in the Dorset County Asylum a patient was found within the last few days brutally beaten into insensibility by one of the warders.

Such occurrences should be not only improbable but impossible, and nothing but vigilant watching and enforced publicity can make them so. We want some better security against abuses than is afforded by the three monthly official inspections from the Castle, and the good intentions of resident officers who are, practically, responsible only to themselves. We have no distrust of the resident Medical superintendents, nor, despite an occasional disclosure like that at Limerick, have we any reason for such a feeling; but "doctors are but men," and they must be something more if they are to be expected to resist the temptation to do what they like when—if the day ever comes—there is no one to look at them.—ED. M. P. & C.]

TRANSACTIONS OF THE PATHOLOGICAL SOCIETY OF LONDON.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your review of the Pathological Society's transactions last week you refer to a case of mine, entitled "Adhesion of the velum pendulum palati to the posterior wall of the pharynx, with loss of the epiglottis, caused by syphilis," in which you incline to the belief that the lesions were probably caused by struma and not by syphilis. If it had occurred to me that this mistake would have been made, I should have given a fuller history of the case before describing the lesions presented after death. Permit me, however, to supplement the case by adding a few words in your journal which seem necessary to demonstrate the syphilitic character of the disease.

The man was a prisoner in the Manchester county jail, and on his admission was suffering from constitutional syphilis. There was, in addition to a crop of syphilitic maculæ, which persisted after death, extensive circular (syphilitic) ulceration of both tonsils. He was a robust and muscular man, without a trace of struma about him; but after a time the syphilitic inflammation spread to the air passages, giving rise to syphilitic laryngitis, and, subsequently, symptoms of phthisis manifested themselves, which killed him. On inspection after death there was found, besides the peculiar pharyngeal and laryngeal deformation, a large vomica in the apex of the right lung, which I rationally attributed, and still attribute, to the poison of syphilis. I should, perhaps, mention that there was also multiple adenopathy in one groin, and a hard based cicatrix upon the penis.

Your obedient servant,
S. MESSENGER BRADLEY, F.R.C.S.
Longsight Hall, Manchester.

primary examination in
inst :—Edward Roe, F. Champneys, L. D. Bell, C. Curwen, F. G. Hamilton, H. Peevor, and E. R. Hutton, St. Bartholomew's Hospital ; A. G. Buckland and J. B. Ruddock, London Hospital ; E. E. Glyde, Guy's Hospital ; C. N. Griffiths, King's College ; W. G. Rountree, University College ; J. R. Ogle, Birmingham. Of the 104 candidates examined on the 14th, 15th, and 16th inst., 42 failed to satisfy the Court of Examiners, and were referred to their anatomical and physiological studies for three months.

College of Physicians, Ireland.—At examinations held on Jan. 14th, 15th, and 16th, the following gentlemen obtained the licences in Medicine and Midwifery :—*Medicine*—Edward Bowers, Andrew John Brady, Charles Edward Piers, Gabriel O'Connell Fitzsimon Redmond, James Shaw, Charles Catterson Smith, John Richard Henry Sutton, Samuel Henry Webb. *Midwifery*—Andrew John Brady, Gabriel O'Connell Fitzsimon Redmond, James Shaw, Charles Catterson Smith, John Richard Henry Sutton, Samuel Henry Webb.

Medical Officer of Health for Nottingham.—For this appointment (salary £400 a year) thirty-four candidates presented themselves. Four of them have been selected for final decision on the 3rd of February.

South Staffordshire Hospital.—The working men of Wolverhampton, on a recent Saturday, presented a sum of £1,500 to the South Staffordshire Hospital, as a contribution to the expense of the extension of the hospital by the erection of a fever hospital and of two new fever wards. This is in addition to £500 contributed by the working men in the beginning of the year, and £200 more is said to be expected.

A Lady Poor-Law Inspector.—The Local Government Board is reported to have appointed Mrs. Nassau Senior as one of its inspectors, at a salary of £400 a year, for the purpose of looking after the domiciles and the treatment of children who are boarded out.

Death from Nitrous Oxide Gas.—An inquiry was held at Exeter, on Jan. 23, into the death of Miss Ada Wyndham, a relative of Baron Channell's, who met her death whilst under the influence of nitrous oxide gas, administered for a dental operation. She was an unmarried lady, 38 years of age, residing at Manor House, Seaton, and in consequence of an appointment with Mr. Browne-Mason, surgeon dentist of Exeter, she came here yesterday morning to have her teeth examined. He told her it would be necessary to have one extracted, when she expressed herself willing to undergo the operation, but said it must be under the influence of gas, which gas was administered in the presence of her own Medical attendant, but as the pulse soon became weaker the gas apparatus was withdrawn, and the operation proceeded without its aid. Miss Wyndham said she could not bear the pain, and wished to have the gas again administered, and when about six gallons had passed through her lungs she was insensible, and the tooth was thereupon split and extracted. Just as the pieces were all removed a lividity of the features was noticed ; the dentist and the family physician became alarmed ; restoratives were administered, and the assistance of another surgeon having been obtained, everything was done to restore animation. The features, however, became swollen, the tongue protruded, there were indications of convulsions, and in about five minutes afterwards the pulse ceased to beat, and death ensued. The nitrous oxide was composed of about four parts of nitrogen to two parts of oxygen. The deceased lady was of rather full habit, yet she had such a remarkably broad chest, and the heart and lungs were both so healthy, that Dr. Drake, the physician who was called in, said he did not think that the corpulency would in this case have been in any one's judgment an objection to the use of the gas, and which was very generally administered in dentistry, and he had never before heard of a fatal result. The cause of death was paralysis of the part regulating the breathing, arising from the administration of the gas. He did not think that any forethought could in this case have prevented the result, if the gas was once administered. The Coroner (Mr. Hooper) remarked that the death was of a very novel character. The question for very careful consideration was, whether or not Mr. Mason administered the gas with due care, and after making all necessary inquiries, as he appeared to have done, it would be a case of homicide by misadventure, if he had not done so it would have been a case of manslaughter. The Jury returned a verdict of "Homicide by Misadventure," and expressed their unanimous opinion that every precaution was taken by Mr. Mason.

London International Exhibition, 1873.—The third meeting of the Committee on Surgical Instruments and Appliances was held last week, at which the following members were present:—Mr. Cæsar H. Hawkins, F.R.S. (in the chair), Dr. P. Allen, Mr. R. Brudenell Carter, Mr. W. White Cooper, Sir Wm. Fergusson, Bart., F.R.S., Dr. Arthur Farre, F.R.S., Dr. G. T. Gream, Mr. Prescott Hewett, F.R.S., Mr. J. Hinton, F.R.S., Mr. J. Luke, F.R.S., Mr. T. W. Nunn, Dr. W. S. Playfair, Mr. Edwin Saunders, and Mr. Edwin Sercombe. Major-General Scott, C.B., Secretary to Her Majesty's Commissioners, attended the meeting. The committee considered the following resolutions, which were passed at a meeting of London surgical instrument manufacturers held on the 10th inst., Mr. Louis Blaise in the chair:—(1.) "That the surgical instrument manufacturers do not exhibit unless the conditions requiring their manufactures to be submitted to a committee of selection be withdrawn." (2.) "That they may exhibit all the articles of their manufacture as a whole, and not in sections or subdivisions, as proposed by Her Majesty's Commissioners." (3.) "That the condition on which the foreigner and Englishman exhibit shall be one and the same." It was recommended that a reply should be sent explaining that English and foreign exhibitors would, as always intended, be on precisely the same footing; that it is not proposed to separate an exhibitor's instruments into sections or subdivisions; and that, while it is unadvisable to dispense generally with the principle of acceptance on the approval of a committee, an assurance of admission might be given by the committee to manufacturers of very high repute who should notify their desire to exhibit. The committee was informed that Signor A. Castellani, of Rome, had commenced to make exact reproductions of the surgical instruments found at Pompeii, and that the Japanese Minister, Terashima Munerero, himself a physician, had promised to obtain a collection of surgical instruments from Japan. Letters were read from Sir Alexander Armstrong, K.C.B., Sir John Rose Cormack, M.D., of Paris, the Royal College of Surgeons, Royal College of Physicians, University College, and the University of Edinburgh. The committee then adjourned till Monday, the 17th February.

Gleanings.

Asbestos.

THE name of this indestructible compound is derived from the Greeks. "Asbestos" literally means "unburnable"—a title which is very thoroughly earned by this strange substance. It is, moreover, so unassailable by all known solvents that it is a virtual impossibility to analyse and give its component parts with exactness. Enough, however, is known or guessed at to enable us to speak of it as consisting of from 50 to 60 parts silex, 10 to 20 parts magnesia, about the same proportion generally of aluminium, some traces of protoxide of iron, and occasionally a lime-like mixture. These proportions vary greatly in the hundreds of different varieties of Asbestos known, and govern and regulate exactly its value for practical purposes. Asbestos is a mineral. It is found in nearly every part of the world, and occurs in distinct veins and seams, usually in the serpentine formation of rocks. In order to procure it, it is necessary to mine in regular form, and to work the lodes or seams by blasting and tunnelling. This, in many cases, is a very costly process, as the rock in which it is found is extremely hard. The seams vary greatly in size, width, colour, and general appearance in different parts of the world. In fact, no two are exactly alike, but they have almost universally the same dip and inclination.

The marvellous properties and consequent prospective value of Asbestos to mankind have been known to some extent and appreciated for thousands of years, and vast sums of money have been expended in endeavours to make it available; but, up till within a few years, these experiments have for the most part resulted in failure, from the fact of the varied and dissimilar peculiarities of the different species—such, for instance, as the length, strength, and fineness of the fibre, excess of magnesia, or aluminum, &c., being unknown. The practical uses to which it is not only possible but probable that Asbestos will be put are almost numberless. Occupying as it does the position of a connecting link between the animal, vegetable, and mineral kingdoms, and possessing the properties of all, scarcely too much can be claimed for it in regard to its adaptation to appliances. Asbestos boats, tubs, boxes, waggon bodies, and even railway carriages, which will neither rot, burn, nor splinter, are perfectly practicable and possible. In fact, so varied and peculiar are the qualities of Asbestos, and so adaptable is it to the wants of mankind, that it may be looked upon as the "coming material." There is already a large company established in Glasgow to "work" Asbestos for the home and foreign markets.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this request.

All communications intended for insertion must bear the name and address of the writer; not necessarily for publication, but as a voucher of good faith.

SUBSCRIPTIONS IN THE UNITED STATES.—A correspondent has drawn our attention to the fact, that some of the houses in the United States are charging the enormous figure of 15 dollars per annum (more than £3) for supplying this Journal to different parts of the States. We beg, therefore, to state that we shall be happy to supply the same regularly, post free, per annum, if paid in advance, for considerably less than half this amount, viz., six and-a-half dollars (about £1 6s. 0d.), either direct from our offices in this country, or through our recognised agents in the United States.

NOTICE TO SUBSCRIBERS.—Subscribers who desire to avail themselves of the reduced tariff, by paying for the year in advance, must please send in their subscriptions before the end of the present month, otherwise the usual rate for credit will be charged.

MANUFACTURERS AND THE ADULTERATION ACT.—Since the passing of this Act, which, as is always the case when a law is made to check dishonesty, presses unfairly upon the honest manufacturer, various means have been devised whereby articles of food of genuine composition may not lie under suspicion in consequence of the manufacturer declining to specify the exact components. Few articles have perhaps been more systematically adulterated than cocoa, and our readers will remember, in our "Food Reports," we more than once exposed the presence of brick-dust and other not very desirable or digestible ingredients. The Messrs. Cadbury Brothers, the well-known manufacturers, have just issued a Circular to the Profession and the trade, in which they state that—"Since the passing of the new Adulteration Act, we have seriously considered the importance of clearly stating what articles are pure and what are mixed. We have, therefore, placed them under two distinct heads—namely, Cocoa and Chocolate. Those we call cocoa are guaranteed to be manufactured of pure cocoa, without admixture; and those under the head of chocolate, are mixed more or less with other wholesome ingredients." This is as it should be.

MR. W. H., Bristol.—We think the Respirator about which you ask our opinion a very ridiculous contrivance. It is not a respirator in any sense of the word, and the fact that two of our contemporaries have *puffed* the said article as a "New Invention" does not deter us from giving an honest opinion. Not *very many weeks* ago our attention was drawn to the fact that, in two contemporaries, under the heading of "New Inventions," a highly laudatory article appeared on "Whiskey," which was neither new nor better than the ordinary spirit. In the same number appeared a page advertisement of the article.

DR. DALE, Plymouth.—Your note has been forwarded to the proper quarter, with a request for a private reply.

DR. BLACK is thanked for his complimentary letter. Such genuine expressions of approbation from subscribers are encouraging in an uphill warfare against trade influences and cliquism.

ST. ANDREW'S GRADUATE.—A General Session will be held at the Freemasons' Hall, London, on Saturday, the 8th proximo. The Annual Dinner will be given at 6·30 the same evening, after an address by Dr. Lyon Playfair, M.P.

DR. JACOB'S Communication "On the Treatment of Soft Cataract by the Operation of Solution," is unavoidably held over until our next.

COMMUNICATIONS, Enclosures, &c., received from Dr. Anstie, London. Dr. de Pascale, Nice. Dr. Palfrey, London. Dr. Cirillo Bonzoni, Padone, Holland. Mr. Cole, C.B., Kensington. Dr. Gavin, Boston, America. Mr. A. Bibby, Jersey. Mr. T. M. Dixon, Nottingham. Dr. Nottingham, Liverpool. Dr. Redman, Lincoln. Dr. Thorowgood, London. Dr. Handsel Griffiths, Dublin. Dr. Pritchard, Northampton. Dr. Morgan, Dublin. Mr. Robinson, Putney. Dr. Langley, London. Mr. Arnold, London. Dr. Drysdale, London. Dr. Ballard, Huntingdon.

Mr. Sloane. Forest Row. Rev. Alex. D. D'Orsey. Mr. Cochran, Paisley. Dr. Carpenter, Amersham. Dr. Barr Meadows, London. Mr. Biddell, Croydon. Dr. Parker, Whitchurch. Mr. Douglas, Shrewsbury. Mr. J. A. Letts. The Secretary of the Medical Society of London. The Secretary of the Pathological Society of Dublin. Dr. Butler, Philadelphia. Dr. Bathurst Woodman, London. Mr. J. L. Hughes, Dublin. Dr. Hime, Sheffield. Dr. Balfour, Edinburgh. Dr. Roberts. Mr. Dickinson, Preston. Mrs. Baines, London. Dr. Kraus, Paris. Mr. Hutchings. Dr. Davies. Dr. Gordon, C.B., Dover. Mr. Walter Rivington, London. Dr. Richardson, Dublin. Dr. Johnston Scott. Dr. Kennedy. Dr. Hayden. Dr. Jacob, Maryborough, &c.

Deaths.

BODKIN.—On the 23rd January, at Park Villas, Selhurst Road, South Norwood, Thomas Bodkin, M.R.C.S.

HUDSON.—Accidentally drowned, on the voyage to Calcutta, Robert Ponsonby Hudson, L.R.C.S.I., aged 25.

LYNCH.—On the 15th of January, Daniel Lynch, M.R.C.S.E., of Belgrave Terrace, Higher Broughton, Manchester, aged 68.

MILBANKE.—On the 16th of January, at King Henry's Road, South Hampstead, R. T. Milbanke, Army Surgeon, half-pay.

NUTTALL.—On the 17th of January, Francis Nuttall, Surgeon, of Bury, aged 44.

SHAW.—On the 17th of January, at East Park Terrace, Southampton, R. Shaw, M.R.C.S.E., late H.E.I.Co.'s Bengal Service, aged 80.

ALBUMINURIA.

In some clinical remarks at Guy's Hospital reported in the *Lancet*, Dr. Wilks observed that albumen may appear in the urine as the result of a cold. The explanation of this seems to be that the cold sets up in the uriniferous tubules a condition closely resembling that found in the bronchial tubes when they are effected. When the kidney recovers itself the albuminuria disappears But a cold may give rise to acute tubular nephritis ; and even this may be recovered from. The albuminuria dependent on the inflammation produced in this manner is very different from that which occurs as a result of a chronic degenerative change in the tubules of the kidney, which is itself often only a part of a general condition. Their respective prognosis are different. It is difficult to say the exact time at which albuminuria, as a result of acute tubular nephritis, becomes incurable. There is no doubt that many persons who have been condemned have recovered. Dr. Wilks formerly thought that if dropsy and albuminuria, as a result of acute tubnlar nephritis, lasted six months, cure was impossible. But he thinks so no longer; for he has seen cases recover after a much longer than this. One of the first places in which dropsy, as a result of renal disease, shows itself is the subconjunctival tissue. Drs. Bright and Barlow always looked to the conjunctivæ when kidney disease was suspected, ard laid great stress on the presence or absence of œdema os this part. When œdema is present the conjunctivæ look bright and glistening, and the eyes appear suffused with tears ; but an examination will show that the fluid is beneath, and not upon, the mucons membrane.

INDIAN MEDICAL SERVICE.

NOTICE is HEREBY GIVEN, that an EXAMINATION of CANDIDATES for appointments as Assistant Surgeons in Her Majesty's Indian Medical Service will be held at Burlington House, London, on the 17th February, 1873.

Copies of the Regulations for the Examination of Candidates, together with information regarding pay and retiring allowances of Indian Medical Officers may be obtained on application at the Military Department, India Office, Westminster, S.W.

T. T. PEARS, Major-General,
Military Secretary.

Military Department, India Office,
8th January, 1873.

WEST RIDING ASYLUM, WAKEFIELD.—WANTED immediately a Clinical Assistant who will have to take notes of Cases and aid the Medical Officers generally in the discharge of their duties, and who will be provided with furnished apartments, board, &c., in return for his services. To any one desirous of entering the department of lunacy practice, or of learning something of the treatment of mental and nervous diseases, this appointment offers singular advantages, as the Asylum contains 1,400 patients, and affords every facility for study and observation.

Applications, with a Certificate as to moral character, to be sent to me on or before the 30th inst.

J. CRICHTON BROWNE, M.D., Medical Director.
West Riding Asylum, Wakefield, 20th January, 1873.

DUNFANAGHY UNION, CROSSROADS DISPENSARY DISTRICT.

MEDICAL OFFICER WANTED.

THE COMMITTEE of MANAGEMENT of the CROSSROADS DISPENSARY will, at their Meeting on WEDNESDAY, the 5th of February, at 12 o'clock, in accordance with the sealed order of the Local Government Board, proceed to elect a SECOND MEDICAL OFFICER for said District, at a Salary of £100 per annum, exclusive of Vaccination and Registration fees.

Testimonials as to character and competency to be lodged with the Honorary Secretary, before the day of Election.

Personal attendance of Candidates necessary, and the person elected must reside at Falcaragh, or immediate neighbourhood.

Application to be made to the,

Rev. V. P. GRIFFITH, Hon. Sec.
Falcaragh, Letterkenny, Jannary 16th, 1873.

THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.

Patron:—H.R.H THE PRINCE OF WALES.

This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour, by the most improved methods to develope the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £35 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote.

Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c., can be had at the office,

40 MOLESWORTH STREET, DUBLIN,
W. O'NEILL, Secretary.

Irish Poor-Law Intelligence;

UNDER AUTHORITY OF THE

IRISH MEDICAL ASSOCIATION.

MONAGHAN BOARD OF GUARDIANS.

The following letter was read :—

"Sir,—On the 15th instant, at Dr. Irwin's desire I met him in consultation on a midwifery case in Scotstown Dispensary District, and, as the patient was attended under the Poor-law Medical Relief Act, I beg to apply to the Board of Guardians for my fee, viz., £2 2s.

"Your obedient servant,
"W. Woods, Physician, &c."

The Chairman—Well, you must write to the Local Government Board on the subject.

Colonel Lloyd—If it was a very intricate case, I think he was justified in obtaining assistance; but I do not know who should pay for it.

The Chairman—I do not know whether Dr. Irwin ought not to pay the fee himself.

The Clerk—Dr. Irwin himself spoke to me on the subject, and I told him we never had such a case in the Union before.

Colonel Lloyd—I would have nothing to say to the matter, but I would allow the gentleman to apply to any source he likes for payment.

Mr. Taylor—I think before we entertain the application we should ascertain that there was a real necessity for assistance.

Colonel Lloyd—I would acknowledge the receipt of the letter, and say that the Board did not feel inclined to entertain the application. That would only be courteous.

The Chairman—Say that the letter was brought before the Board, and that they decline to entertain it.

Mr. Watson—That is the simplest way of acting.

Colonel Lloyd—I think this is the last we shall hear of it.

PAYMENT OF MEDICAL SUPERANNUATION FROM THE CONSOLIDATED FUND.

POOR LAW DEPUTATION TO LORD HARTINGTON.

A very large and influential deputation attended at Dublin Castle on Wednesday, at four o'clock, for the purpose of presenting two memorials to Lord Hartington, for the purpose of obtaining repayment from the Treasury of half the salaries of clerks of unions in Ireland, and half the superannuation allowances of Poor Law Medical officers.

Mr. Myles, Vice-Chairman of the Limerick Board of Guardians, referring to the second memorial, that with regard to the Medical officers, observed that the Consoildated Fund paid half the salaries of these officials originally, but other enactments passed last session to give them superannuation, the expenses of which was cast on the local rates. He thought the cost of this superannuation should also be borne by the Consolidated Fund and by the ratepayers.

Major Ellis and Dr. Peebles also urged that these duties were of an Imperial character.

Mr. George Morris, J.P., said that clerks of unions were originally appointed to perform duties solely connected with the relief of the poor, at very moderate salaries.

Lord Hartington, after referring to the case of the union clerks, said—With regard to the second memorial the case is different. I think there is something objectionable in principle to superannuation allowances being contributed to from Imperial funds. I am informed by the Vice-President of the Local Government Board, that even as it is he does not think there is any undue reluctance on the part of the Boards of Guardians to consider favourably—most favourably—the claims of their officers to superannuation; and, of course, it is clear that any liberality—any tendency to undue liberality—would perhaps be increased if the burden were divided between the ratepayers and the Imperial Exchequer. I do not know that I can do more now than to lay the whole subject before Government, which, indeed, will be glad to have an expression of the views of so many influential gentlemen, who take an interest in the administration of the Poor Law Board in this country.

CLANE DISPENSARY.

On Monday last a large meeting of the committee of management of the Clane and Timahoe dispensaries, after a close investigation, unanimously resolved to increase the salary of the Medical officer, Dr. Smyth, to at least £125 a year, and especially requested the chairman, P. Sweetman, Esq., J.P., to strongly recommend the board of guardians to sanction the proposal.

HEALTH OF DUBLIN AND THE SUBURBAN DISTRICTS.

The deaths registered in the Dublin District during the week, represent an annual mortality of 30 in every 1,000 of the population. In London the death rate was 18, in Glasgow 25, and in Edinburgh 17.

In the Dublin District the births registered amounted to 164. The average was 152.

The deaths were 184, the average being 186.

The number of deaths from zymotic diseases registered during the week was 22, viz.:—5 from fever (4 typhoid or enteric, and 1 simple continued fever), 4 from measles; 3 each from croup, whooping-cough, and diarrhœa; 1 each from scarlet fever, erysipelas, &c.

Thirty-four deaths resulted from bronchitis, and 1 from pneumonia.

Two deaths were caused by epilepsy, 1 by apoplexy, and 1 by paralysis.

Fourteen children died from convulsions.

Heart disease caused 12 deaths, and liver disease 3.

Twenty-six deaths resulted from phthisis, 4 from hydrocephalus, 3 from scrofula, and 2 from mesenteric disease.

Cancer proved fatal in 6 instances.

Six accidental deaths were registered, viz. :—2 from fractures and contusions, 1 from scalds, and 3 from drowning.

31st.—Scott, John Moore Johnston, Crumlin Road, Belfast, M.D., 1872, and M. Ch., 1872, Qu. Univ. Irel.

31st.—Ringland, Arthur Hill, 14 Harcourt Street, Dublin, Lic., 1871, and Lic. Midwfy., 1871, K. Q. Coll. Phys. Irel.

SLIGO BOARD OF GUARDIANS.

THE APPOINTMENT OF APOTHECARY.

The Chairman asked to be shown the advertisement issued by the dispensary committee in reference to the appointment of an apothecary.

The clerk produced it.

Chairman—I see that the candidate must produce certificate of midwifery. Can you tell us, Mr. Homan, why this is asked for?

Mr. Homan—It has been the case always.

Mr. Kerrigan —why? Are not apothecaries merely compounders of medicine? The porters in the country do it.

Chairman—I cannot see why this is called for. Apothecaries are supposed to be only compounders of medicine.

The clerk supposed that licensed apothecaries might have this qualification.

Mr. Kerrigan—They do not require it to make up the prescriptions—to give out the saltz and sena and castor oil, medicines most generally used.

The chairman expressed regret that there was no explanation on the subject.

The Clerk read the minutes of the Sligo dispensary meeting on the 17th instant, which were confirmed in the usual way.

The following letter was also read on the subject :—

"Local Government Board,
"Dublin, January 20, 1873.

"Sir,—The Local Government Board have to inform the Board of Guardians of the Sligo Union that they have received the minutes of proceedings of the committee of management of the Sligo dispensary district, at the meeting held on the 17th instant, for the purpose of appointing an apothecary for the district, from which it appears that no candidate under the age of forty years having offered himself for election, a resolution was adopted by the committee that application be made to the Local Government Board 'to ascertain the limit of age they will sanction for the information of the Board of Guardians on Tuesday next, when the whole subject will be re-considered.' In reference thereto, the board have to state that their regulations do not limit the age beyond which candidates cease to be eligible for the office of apothecary; but at the same time when making a selection amongst the candidates for the office in question, the committee would do well to take their ages into consideration, and not appoint a person of advanced years who might not be able to discharge the duties of the office in person, and who in a short time, from infirmity, would probably seek superannuation and become a burden on the rates.—By order of the board,
"B. Banks."

Mr. O'Connor thought the best thing to do would be to appoint Dr. Johnston.

Chairman—That seems to be more within the province of the Dispensary Committee.

Mr. Doherty—No candidate sent in his testimonials to the committee. Dr. Johnston did not send in his testimonials, and the committee could not go outside the terms of the advertisement—otherwise Dr. Johnston would have been elected the day of the meeting. You must either appoint Dr. Johnston at £80 a year, or raise the salary to £100.

Mr. M'Gill—Since the meeting on Friday three gentlemen all duly qualified wrote to me, saying they would take the dispensary at £100 a year, but not less.

At the suggestion of the chairman, it was resolved that the letter be forwarded to the Dispensary Committee, with the view of enabling them to act to the best of their judgment in the matter.

SLIGO DISPENSARY COMMITTEE.

A special meeting of this committee was held for th purpose of electing a qualified apothecary, pursuant to advertisement, and for the transaction of other business.

The Honorary Secretary read the minutes of last day's proceedings directing the letters of Drs. Tucker and Maguire to be laid before the Local Government Board, and inquiring how the Committee should act in the matter.

Mr. M'Gill said the meeting had been called for the election of an apothecary. No candidate had applied.

Mr. Doherty—Have you got any communication?

Mr. M'Gill—One gentleman wrote for a list of the Committee, but he had not heard from him since.

Mr. M'Gill read the following letter :—

Dublin, January 16, 1873.

Sir,—I am directed by the Local Government Board for Ireland, to acknowledge the receipt of your letters of the 10th and 13th inst., inquiring—by direction of the Committee of Management of the Sligo Dispensary District—how they should act in regard to the leave of absence recently granted to Dr. Tucker (Medical Officer), and to the appointment of his substitute, Dr. Tucker having resumed the discharge of his duties the day after leave had been granted to him; and in reply I am to state, for the information of the Committee, that it was quite competent to Dr. Tucker to resume the discharge of his duties, when he felt himself able to do so.

B. Banks.

Dr. Ferguson said as no candidate had come forward he would move that Dr. Johnston, who had been employed, and who had given satisfaction, be continued as apothecary. He was willing to undertake the duties at a salary of £80 a year. Under the circumstances they might as well appoint him.

Rev. Mr. Griffith—There is some condition about the age. It is competent for us to withdraw the limit.

Mr. Conry—If the Local Government Board permit you. They say they don't want to be giving superannuations.

Mr. Simpson—Was it the Committee who put in the limit of 40 years?

Mr. M'Gill said it was put in by direction of Dr. Roughan, Poor-law Inspector.

Dr. Johnston was then sent for, and on entering the room said he had been in charge for nine or ten weeks, and from knowing the working of the dispensary, he would have no objection to take it at £80. The limit of age prevented him applying.

Dr. Johnston said he was over the age, but he was able to do his duty.

Mr. M'Gill said if the Board of Guardians fixed the salary at £100 a year, they would get a competent person.

It was after considerable discussion, resolved that the Local Government Board be informed that on the day appointed for the election of apothecary, no candidate presented himself, that Dr. Johnston was willing to undertake the duty, and that the feeling of the meeting was unanimous for appointing him, but being above the prescribed age, he could not be appointed, and that the Secretary apply to the Board to ascertain the limit of age, for the information of the Board of Guardians on Tuesday next, when the whole subject will be reconsidered.

OMAGH DISPENSARY DISTRICT.

Illness of Dr. Love.—Dr. Boyle has been temporarily appointed to discharge the duties of Medical Officer of the Omagh Dispensary District during the illness of Dr. Wm. S. Love, who has had a severe attack of fever, but who, we are happy to hear, is now in a fair way of recovery.

PORTRUSH DISPENSARY.

A special meeting of the Committee of the Bushmills and Portrush dispensary district, was held on the 9th inst., for the purpose of electing a Medical officer in room of Dr. Campbell, resigned. There were three candidates—Dr. Blundell, Dr. M'Ilroy, and Dr. A. T. Carson. The latter gentleman was elected by a majority of 15 to 9 over Dr. M'Ilroy—the first named gentleman being put out of the competition in the first.

WATERFORD UNION.

£70 A YEAR FOR OUT-DOOR RELIEF OF A SICK PAUPER.

The Clerk reported that, in pursuance of orders, he had written to Dr. Cane, M.O., Kilmacevogue district, asking to be informed on the ground upon which a woman named Kathleen O'Hara is receiving £1 6s. a week provisionally.

Dr. Cane replied as follows :—

Gentlemen—In reply to your question about O'Hara's case I believe the reason is, destitution and illness.

I might refer you to Act of Parliament, Vic. 35 and 36, cap. 94, and some section, but your valued R.O. is the only person who can reply to that question, as you now put it to me. As it is foreign to my business to meddle in such matters, I trust that your board will not refuse to remunerate me for writing this letter. Also, if Mr. McDermott, the auditor, rebukes me for for meddling in the relief in this case, as I have only done so at your request, I trust that your board will convey me safely in the matter.

Those members of your board who really who do take an interest in the affairs of the sick poor by attending every Wednesday, losing valuable time, have had the case before them each week, and were, all through, fully satisfied, having inquired into it daily, but, of course, the non-attending or absentee members are not acquainted with all the facts of the case. How could they be?

Then came the following from Mr. D. Carroll, R.O., on the same case :—

Gentlemen—In compliance with your request, I beg to furnish you with the grounds on which an old woman, named Kathleen O'Hara, aged 82, is receiving provisional relief in my district.

Five months ago this woman was granted, by the board, two shillings a week on recommendation of Mr. John Fitzgerald, the guardian for the division in which she resides. Five months since, she was visited by the medical officer, who reported that she was very ill, urgently requiring stimulants—beef tea, the constant care of a nurse, and was unfit to be removed. I immediately visited the case, and found her apparently in a dying state, destitute and houseless, and the house in which she had received a temporary shelter, cheerless and damp. Being of opinion that the amount granted was inadequate, viz., two shillings a week, and having fully considered the circumstances of the case, I was of opinion that it was one of sudden and urgent necessity, and afforded such provisional relief as I considered essentially necessary, according to 10th Vic., cap 31, sec. 7.

In strict conformity with sec. 7, I have weekly reported to you the cost, and the particulars of all relief afforded under my provisional power, which you approved. It will be my imperative duty to continue same so long as the circumstances of the case may demand. I regret I cannot comply with the recommendation of the guardians, either to reduce the amount of relief, or to remove her to hospital.

The Chairman said he would now treat them to another letter from Dr. Cane, this time to the relieving officer. Dr. Cane writes, "I would recommend that the allowance of 14 glasses of brandy per week be increased to 20. I would recommend the one pint of milk daily to be made a quart (Mr. Hally was now seated, but glaring threateningly around him) ; I would give her a chicken ; I would also give her 4lbs. of beef for making soup, and I would also give her 3lbs. of beef for frying on a gridiron."

The Chairman observed he did not think if he was relieving officer he would feel justified in giving such a quantity as twenty glasses of brandy. If it was given it might not be a matter of wonder if the relief should abruptly terminate.

The observations ended without a resolution, the guardians being officially powerless in the matter.

The Mayor said that his chief object in attending the board that day was to ask instruction as to some matters connected with poor relief arising in some cases before him. The case to which he would principally wish to refer was as follows :—On Monday a child died in a very bad state of scarlatina, and in a very destitute condition. When high-constable Pallas, sanitary officer, went to the house, the parents had no coffin in which to put the little body, nor had they any means to procure one. Means were given them to obtain a coffin, but they did not seek for it in time. It was not until the body was in a putrid state that one was brought, through their default, and the high-constable was forced to put the body into the coffin with his own hands, those around being too drunk to do anything, having got subscriptions in the locality for the funeral. He (Mayor) directed to have the coffin nailed down, and he gave Mr. Pallas half-a-crown to have a car to bring the body to be interred. Now his (Mayor's) wish was not to come into the slightest collision with the guardians in carrying out the Sanitary Act, but rather to act under their guidance, and he would now be glad to know what was the exact course he should have taken in the matter, and if there was a special place set apart for the reception and the interment of such bodies?

DREADFUL AFFAIR AT LIMERICK LUNATIC ASYLUM.

On Friday evening last a patient in the above establishment named Kenna, while engaged in visiting a mason in repairing the furnace in the Turkish Bath department availed himself of the absense of the latter to set fire to his clothes. On the return of the mason he found the unfortunate creature enveloped in flames. He made an immediate alarm, and had assistance procured, when an effort was made to save the poor man's life by tearing his clothes off him. He, however, violently resisted, and appeared to desire to be allowed to burn to death. Dr. Fitzgerald, the Medical superintendent, was quickly in attendance and seeing the precarious condition of Kenna, sent for the Medical consultant, Dr. Gelston who in a short time arrived. Every effort was made to restore the sufferer, but all failed, for he expired last evening. Kenna was 45 years of age, and spent 15 years in the asylum. He was always looked upon as a harmless imbecile, and never exhibited any symptoms of a tendency to destroy his life up to the time of the present melancholy occurrence. An inquest was held on the body next day by Mr. Coroner Costelloe.—*Limerick Reporter.*

On January 15th, at his residence, Home Hill, Bridge of Allan, Wm. Gordon, Esq., M.D., late of Strabane, aged 51 years.

On January 9th, in Dublin, John Dowse, son of Dr. Langley, of Tramore, aged 17 years.

On January 16th, at Portobello Barracks, Dublin, the wife of Staff-Surgeon Wm. T. Harding (son-in-law of Dr. Owens, J.P.), of a daughter.

On January 14th, at Clogheen, the wife of Dr. Fenton, of a daughter.

THE REMOVAL OF CATARACT BY SOLUTION, ESPECIALLY WITH REGARD TO THE SOFT CATARACT OF EARLY LIFE, AND THE OPERATION BY KERATONYXIS.

BY ARCHIBALD HAMILTON JACOB, M.D.Dub., F.R.C.S.I.,
Chief Surgeon to the Dublin Eye and Ear Infirmary; late Ophthalmic Surgeon to the City of Dublin Hospital.

(*Continued from page* 524, vol. xiv.)

I HAVE stated in a recent publication (MEDICAL PRESS AND CIRCULAR, December 18th, 1872, page 524) that "in the majority of cases, I operate by extraction, with the feeling that my doing so, is a concession to the convenience of the patient, and that I thereby purchase a comparatively rapid restoration of sight at the expense of a very grave risk of failure, and a certain inevitable sacrifice as regards the ultimate result. I am perfectly persuaded that in almost *all* cases of true cataract, hardly even excepting those of hard amber cataract of old age, it would be my duty to advise the operation of solution in preference to that of extraction, if the patient were content or able to wait for the result."

In making this exception, however, I do so, not because a hard senile cataract is incapable of being resolved by the operation of division, but because the lengthened period which is required for complete solution goes somewhat to justify the more riskful operation of extraction. Cases of hard amber cataract may present themselves, in which an excision operation is not admissible, in consequence of some constitutional fault in the patient, or in which the patient is content to wait for the result rather than encounter the risks of the extraction operation, and it should be remembered that in such cases restoration of sight is quite feasible if the patient will wait some months for the result. About three years ago an old lady of seventy-four consulted me as to the removal of her cataracts, which were of the usual dark-coloured waxy type, and fully developed in one eye. She was the victim of constant and prolonged attacks of bilious vomiting, which it did not appear could be controlled, and was, moreover, in such a state of health that confinement to bed, or prolonged suffering, might probably be attended with much risk to life. I advised her that none of the speedy methods of removing her cataract were available in her case, but gave her the alternative of an operation for division, assuring her that most probably she would be no worse a week after the operation than she had been before, and that she might confidently hope for restoration of vision within a year. I operated on that lady's lenses, which were as hard and waxy as I ever met, and after three repetitions of the operation, none of which were attended with any ill effect whatever, she was rewarded by a perfect recovery, and she now sees perfectly well. Late writers have expressed themselves as if they held the opinion that not only was the absorption of a hard senile cataract tedious, and, on that account, the division operation inapplicable, but that such a method of treatment was totally out of the question in old persons. I desire, if possible, to remove this misconception. I have seen in my father's practice many, and, in my own, a few hard amber cataracts removed without risk or discomfort, by one or two insignificant operations.

The extreme slowness of absorption, and the necessity for repeated disturbance of the eye in a person advanced in life are, however, sources of inconvenience and risk which justify the selection, as a rule, of the more hazardous operation in cases of hard senile cataract, and I quote the foregoing case to show that under exceptional and even very unfavourable circumstances, the cataract of old age may be removed by division, and will dissolve even after a single breaking up if abundance of time be allowed for the process.

There are several forms of capsular or lenticular disease which are included under the name of cataract which are not amenable to the absorptive treatment, and cannot, therefore, be included in the favourable opinion of that method to which I have given expression. These are:—1. The calcareous or osseous cataract; 2. The pyramidal; 3. Extensive capsular opacities; and 4. The false or cheesy cataract which arises from the deposit of products of inflammation upon the surface of the capsule or within the pupil.

If, indeed, the capsule be to a considerable extent involved in the disease, or if it is adherent to the iris to such extent as to make it a matter of difficulty to detach it and displace it from the field of vision, it is probable that a subsequent operation may be necessary for its removal. In a former communication I have described the necessary procedure for that purpose, which, if it cannot be dispensed with, is neither difficult nor dangerous; whilst if the capsular opacity be slight, there will be no difficulty in getting rid of it by displacing it with the needle during the operation of division. The calcareous, or, as sometimes described, the osseous cataract, which is illustrated after Mr. Wardrop's delineation in Fig. 1, is a not infrequent result of chronic degenerative inflammation, and is formed by the deposition of calcareous matter on the exterior of the capsule, sometimes of both the anterior and posterior surfaces. Rarely also the tendency to true osseous deposits which results in the laying down of bony plates on the surface of the choroid, is said to determine similar formations in the lens. I have recently extracted a calcareous mass formed of an anterior and posterior plate corresponding to the front and back capsular surfaces, and connected by a net work of calcareous trabeculæ, the interstices of which were filled up with softened lens matter.

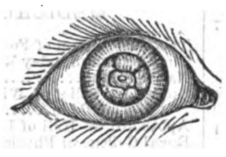

Fig. 1.

A lens which has undergone calcareous degeneration can obviously be disposed of neither by division nor displacement, not being susceptible of absorption in the one case, and from its weight and irregular form, very unsuitable for depression or to be permitted to remain as a foreign body within the fundus. Being the product of chronic deteriorative inflammation it is usually accompanied with a fluid vitreous humour and other sequelæ, such as would make the extraction operation riskful, and the benefit derivable from it doubtful. In the case of which I have spoken above the retina turned out to be faulty, and but slight improvement was achieved.

The pyramidal cataract, of which I reproduce Mr. Wardrop's representation in Fig. 2, is an extremely rare form, and, as depicted in the illustration, bears the appearance of an elongated cartilaginous pyramid fixed firmly on the anterior surface of the lens. It is considered by Stellwag to be identical with the more common central opacity of the capsule, except that the deposited matter is built up by successive layers behind, and is pushed forward into a pyramidal shape through the pupil. A single and very remarkable case of this disease came under my notice two years ago, in a child in which both pupils were occupied by two white cartilaginous-looking cones, one somewhat longer then the other. In the natural state, the pupil, which was abnormally contracted, was entirely occluded, and there was hardly any sight; but on dilating it, the base of the pyramid appeared to be the only opaque spot on the capsule. Having introduced a cataract needle through the cornea I found the pyramid perfectly hard, and, on a little pressure, it became detached from the lens and fell into the anterior chamber, whence I was obliged to remove it by a small incision. Within a few days the entire lens became cataractous, evidently in consequence of the laceration of the capsule and admission of the aqueous humour, and it was afterwards successfully removed by keratonyxis. I think this proceeding, though involuntary in my case, would be safer than proceeding to extract in the first instance.

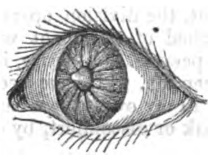

Fig. 2.

Extensive capsular opacities, with or without lenticular cataract, frequently cannot be treated satisfactorily by division without subsequent removal of the capsule. Nevertheless, I have usually treated them by that procedure in preference to linear extraction. I have found that the needle may be used with great freedom in such cases, because the capsular sac is tougher than usual, and if it be freely torn in all directions it will generally shrink out of the field of vision, and when the lens substance has been dissolved will leave a good open pupil and almost perfect vision. Secondary cataracts in such cases seldom give trouble, because, as no adhesions to the iris exist, the capsule has not prevented from retracting up towards the canal of Petit.

A peculiar and unusual form of the capsulo-lenticular cataract is the fluid cataract or *cataracta lactea*. The appearance of this form of the disease is shown in Fig. 3. In it the entire lens substance breaks down into a chalky fluid which is enclosed in the complete capsule which, in itself, is commonly a network of opacity. The fluid cataract is not difficult to distinguish, and on piercing it with the needle the miky contents are evacuated, filling the anterior chamber and completely obscuring the patient's sight and operator's view. In a couple of days this milky *débris* will be absorbed, and the capsular network will be seen *in situ*. The pupil may be cleared of this obstruction either by a liberal use of the needle at the time of the evacuation, or by a subsequent operation. The central cataract is a peculiar form in which the opacity is confined to the nucleus, and to a few fissures which extend to the periphery, but does not differ in any respect from the ordinary capsulo-lenticular form. All the foregoing forms, which are usually congenital or occur in early life, are eminently suitable for the absorption treatment, and they may be dealt with by division through the cornea without the least hesitation, yielding results almost always better than those given by linear extraction and spoon operations, and being, at the same time, attended with little or no risk.

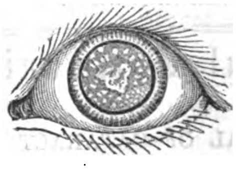

Fig. 3.

The soft stellate cataract, which is ordinarily developed between the ages of 35 and 50, is still more adapted for the operation of division, because it is seldom accompanied by any capsular opacity.

◆

CASES IN MILITARY PRACTICE.

By Mark Anthony, M.D., 47th Regiment, Carlisle.

ALCOHOLISM WITH "RENAL CALCULUS."

Private W., a bandsman in the 15th Regiment of Foot, æt. 24, was admitted in hospital in 1870, in a state of insensibility, and suffering from epileptiform convulsions, repeated every half hour. His head was cool, eyes not congested, pupils of both eyes dilated, pulse feeble, and his breathing was heavy. He appeared to suffer from abdominal irritation, as he constantly put his hand over that region, and writhed in pain if it was pressed.

Previous History.—Has always been a hard drinker; was drunk the night before admission; there is no history of injury, and has never complained of any ailment; was suddenly seized with symptoms enumerated above, in his barrack room, just previous to his admission. The fits continuing, and being unable to receive any further information regarding the patient, it was surmised that the fits were the products of alcoholic poisoning. The treatment adopted was as follows:—The back of head and upper portion of cervical vertebræ was cupped, and subsequently leeched, the summit of head after blistering, was dressed with ungt. hyd., whilst internally his bowels were acted on by croton oil and gruel enemata. Under this treatment, the fits became less frequent, and he recovered consciousness to a slight extent. He lingered in this state for two days, when he became violently delirious, and died.

Post-mortem Appearances.—Brain and spinal cord perfectly healthy looking; lungs and heart also; liver and spleen, waxy; kidneys—the right one was double its ordinary size, but to all appearances in good working order; the left one was small and shrivelled, and contained in its centre an oxalate of lime calculus, weighing 70 grains, with two or three facette on its surface; the bladder was healthy, and contained no calculi.

In this most puzzling case, what was the proposed diagnosis? Was the calculus in kidney the origination of reflex epileptiform convulsions? Did the kidney calculus so far interfere with its functions as to produce the symptoms indicated as a result of uræmic poisoning? or were the symptoms attributable alone to the effects of alcohol circulating in the blood? We have therefore, in this case, three possible causes of the symptoms, anyone of which *per se* is sufficient to explain the mode of attack and death. But who can tell the correct cause? In our utter ignorance, we may solace our professional vanity with the theory that a combination of uræmic and alcoholic poisoning, aided perhaps by the reflex irritant in kidney, was the cause of the man's convulsions and death. Such a case as the above one is most instructive, notwithstanding its obscurity, as it teaches most forcibly how, despite the enormous strides science has made, and the numberless learned theories of disease offered to the world, that at the bedside, the mysterious workings of the human frame are to us of the Medical Profession, often dead letters.

FUNCTIONAL DISEASE OF HEART PRODUCED BY TEA DRINKING.

Was asked by surgeon of 69th Regiment, to see Mrs. S., the wife of Sergeant Major of Regiment. Is a very delicate looking woman, of about thirty-five years of age, and six months advanced in pregnancy at date of visit. Has always had indifferent health generally, which she attributed to an attack of leucorrhœa, incurred several years previous to her marriage. After a little questioning, she confessed to a strong liking for tea, of which article she was accustomed to consume large quantities, by day and night for several years. Her present symptoms are: general and increasing debility, and want of appetite; constipated bowels; palpitation of heart sufficient to drive away all idea of sleep, and prevent her taking any rest on left side; the palpitation is at its maximum, each day at 11 a.m., or thereabouts; she does not feel in the least nervous; has no headache, and never suffered from rheumatism. On applying the stethoscope, the first sound is heard extremely feeble, whereas the second is doubled in a [illegible] way, with no bruit, the impulse is feeble, and there is no extra præcordial dulness; the pulse is [illegible] at the wrists, but feeble.

Treatment.—Ordered to discontinue the use of tea, save in legitimate doses, to have a belladonna plaster over præcordium, and to take thirty minims of tr. ferri. perchloridi *ter in die.* In three weeks under this treatment, the heart sounds became normal, and the patient perfectly well.

ACUTE PERITONITIS.

About three weeks ago I saw the child of Sergeant D., of my regiment, æt. 10 years. She complained of pain in stomach, for which, before coming to me, her mother had given her a dose of castor oil. On the following day, I saw her at her house, when she presented the following symptoms:—Tongue coated with a whitish fur; hot skin; thirst; her pulse was wiry, and 110 per minute; she complained of intense pain in bowels; her abdomen was tense, and the slightest pressure on any part of it produced excruciating agony; she lay in bed on her back, with both legs drawn up, and the respiration was altogether thoracic. For the four following days she had these symptoms, but in an aggravated form, the pulse rising to 130, and the thermometer shewing an average of 103 degrees, night and morning. On the morning of fifth day, she had vomiting and hiccups, with a gasping respiration and pallid countenance, whilst the belly remained as painful as before, but tympanitic. On afternoon of this day, her bowels were copiously moved seven or eight times, after which she slept soundly for some hours, and awoke in a perspiration, with a lessened pulse and temperature.

From this date she gradually improved, and was taken off sick list in three weeks from date of attack. Her bowels throughout had a tendency to be constipated. The treatment adopted, in first two days, calomel, grs. ij., with grs. iij. of Dover's powder, was given every six hours, with an additional dose of grs. iv. of Dover's powder at night time, the calomel appearing to gripe. Dover's powder, grs. v., with vj. of bismuth, was given every five hours till symptoms abated. Stimulants were freely given on fifth day, and lime water and milk as a drink. Bran poultices and turpentine stupes to abdomen, and during convalescence, the syrup of iodide of iron was given. The usual calomel and opium treatment pushed to salivation was dispensed with, as was also leeching, the latter principally from the intensity of abdominal pain, which forbade all manipulation. I have little doubt that a grave amount of enteric inflammation was mixed up with the peritonitis in this case, yet as it is next to an impossibility to diagnose between the two diseases, and as the treatment for one holds equally good for the other, in practice, these anatomical differences are of very little use.

◆

INDIAN MEDICO-LEGAL CASE.

By J. Roche, M.D.,

Assistant-Surgeon, Bombay Army, and Civil Surgeon, Kotrie Scinde.

On the 4th of June, 1870, the writer took charge of the office of superintendent of the Hydrabad jail, in Scinde, from Assistant-Surgeon H——d, from which circumstance a person named Butchal Shah, a Synd priest, in the Mohammed religion, came under his observation. This party had lived in the district of Alyar-ka-tanda, some thirty miles distant from the town of Hydrabad; he was the high priest in the sect to which he belonged. His sway extended into the principality of Kutch, and all over the left bank of the Indus, through the political agency of Thur and Parkur. The office of high priest in the Synds is hereditary, and as they are supposed to be direct descendants of the prophet, it is one of considerable emolument and influence, and commands profound respect from the faithful followers. Butchal Shah was about 40 years of age, and had been married to a woman named Meerzader, of inferior rank to his own (as it is derogatory to a Synd to be allied to any other but a Synd) by whom were born to him two daughters, named respectively Marool and Amnuthi, and who had attained to ages from 7 to 11 years. He had no son, and if no son is born to a Synd priest the sacred office lapses from the family; it is very hurtful to the dignity of these sacred officials to give daughters in marriage to anyone but a Synd; it is, in fact, to tarnish the blood of the prophet himself. The Synds are not, properly speaking, a sect, but a hereditary priesthood, who are supposed to be true descendants of Mohammed; they are worshipped by the sect called Sunees, who retain the sunna or tradition as authentic, as well as the written Koran. They believe that the Sultan at Constantinople is the true head of Islamism, and object to the use of pictures and images in religious typifications as idolatrous, and prefer to give what they consider adoration, and in many cases is such, to the living representative and moving receptacle of the blood of the author of their religion. In these characteristics they differ from the Sheites, or heretic Mussulmen. Butchal Shah had a faithful and devoted servant called Joobher, and as an exception to the assertion that no hero is a hero to his valet, he was his constant attendant, his ministering clerk and ardent disciple.

In the middle of May, 1870, Butchal Shah cut the throats of his wife and two daughters, and put several scars on his own abdomen with a sharp instrument. The act was perpetrated about five o'clock in the morning. Joobher, the servant, seeing the condition of his holy superior all over with blood, and a red knife in his hand, reeking with the steam from the blood of his victims, as well as from that of his own wounds, called the inhabitants and police to the scene. When they arrived Butchal Shah, in an excited manner, conducted them to the bodies of the murdered, and gave no further information to the inquisitors than "That Joobher may have done the deed, or he himself may, but God alone knew."

Nearly all the inhabitants of the town of Alyar were disciples of the Synd, and hence the difficulty in getting accurate information. Butchal Shah was then and there arrested, and brought to the Hydrabad jail, where he was under Dr. H——d's observation and treatment till the 4th of June, when he was transferred to the writer. It is to be here stated that Joobher, after the occurrence, was quickly disposed of, and as he was the only person who could give direct evidence against Butchal Shah, rumour and suspicion hold a different theory from the one stated by the friends as to the cause of his sudden disappearance. When seen by the writer Butchal Shah appeared wild, abstracted, talked incoherently, and would not answer questions directly. He had despoiled his clothes, and torn his hat; these acts infringe specifically on the caste of a Syud, and would point to mental aberration. He was after a few days brought up at court, and his counsel had several witnesses to prove that he was subject to periodic insanity. The apothecary, who was well versed in the signs and symptoms of madness, gave evidence as to the serious nature of the wounds on the abdomen when he was brought to jail, and stated on oath that he considered the man *insane*; the apothecary, however, was a Mussulman and Sunnite. I objected to give evidence, on the grounds that I had not seen the wounds originally, and the man being but a few days under my observation I was unable to pronounce positively on solemn testimony, as to his sanity or otherwise. The case was adjourned for three months, with the view that the party might be closely observed by me, and Dr. N——n, of H.M's 1st Belooches, was specially deputed to visit him, and enquire into his condition, so as to enable him to give evidence in the matter. I will here state that Dr. N——n and myself resolved that this man should have the benefit of the fairest examination, and that one should not tell the other the method he intended or was pursuing, and that we would form our opinions independently and separately, not communicating to each other till we had given our respective testimonies on oath in court, since the man's life depended on our judgments as dictated by our respective reasons, and guided by our respective consciences.

The problem I proposed to myself for solution was, given a man who had outraged society and law by committing the greatest crimes, but the act bears the most marked impress on its face of being due to an impulse from insanity, and this notion is fortified by the strong probability derived from the information given by numerous persons that the prisoner has been subject to fits of insanity, but all of whom believed in him as an earthly divinity, to find whether he is sometimes insane, and if he were sane and responsible for his acts when he did the deeds of blood or not.

Condition of Butchal Shah when seen:—Digestion healthy, pulse 75, countenance morose and fierce, pupils normal, acts tending to violence, and in violation of the amenities of caste, his clothes were daubed, and his hat broken. Would not answer questions, but was declaring that robbers had stolen his property, and that he was haunted by evil genii and a rabid dog. He talked alone and occasionally started as if seized with fear and terror, and sometimes seemed inclined to give way to passion.

To test whether these symptoms were real or affected I subjected his power of fixing his attention, his capacity of reasoning, his memory, and his understanding to ordeal. I also daily noted his health.

1st. *His Attention.*—I asked him every morning questions such as this: *Tunji mai jiethi ya mari viethi* ["Is your mother living or dead"]; no answer, he was apparently abstracted with delusions of devils and robbers. I repeated *jiethi ya mari viethi* ["living or dead"], *juthi ya mari viethi* ["living or dead"], and demanded an answer. After some time he replied *jiethi* ["living"], when I quickly questioned him who was living, and he answered *munji mai* ["my mother"]. This brought me the conclusion that the attention was fixed, the abstraction feigned. For without his attention had been engaged when the proposition was put in its entirety he could not have known the subject were it the predicate alone that elicited the answer.

2nd. *His Reason.*—This I tried by enquiring the nature of a four annas piece, *i.e.* a sixpence, when sometimes he would say "it is an evil spirit," but more than once he said "it is a rupee," and when asked what use it was? what it could buy? he would say "a horse," or "twenty horses."

Now this reasoning bore suspicion strong. There was apparently a knowledge of the value of the coin, and affected illusion and false reasoning by multiplying its value. If an object gives rise to an illusion the illusion is tolerably constant; it was not so in this case.

On the other hand it is to be observed that nearly in all forms of insanity a knowledge of such things as money and food is preserved.

3rd. *His Power of Understanding.*—His understanding I tested by enquiring of him what a grain of bagree (corn) was? What a piece of the bread he used as food was? What a few grains of rice were? When the almost invariable reply I got was "a devil," "a rabid dog," "or an onyx." No matter how the insane suffer from delusions they retain their understanding for such essential things as food, or if they misunderstand them it is in degree rarely if ever in kind.

4th. *His Memory.*—It was by asking him such questions as "if he were married," "had he children," "had he a mother." His reply was "I have not." Very few (if any at all) who ever had reason, and whose attention you can direct that would not remember such marked and striking events as the above refer to.

Those were the questions and answers that passed directly between myself and Butchal Shah, and I concluded he was feigning.

N.B.—He never had epilepsy.

The state of his health I put to test by observing his pupils and digestion daily, and here I will have to dogmatize again, that as the cerebral system is the regulator of the pulse, if it be altered, as it is in insanity, though the pulse may not vary as a constant, shall the patient be subjected to the conditions which disturb the action of the heart, the responding alteration must be greater in the insane than in the sane. This will not hold good if the action be so great and violent as to supplant altogether the controlling power of the heart. I took his pulse daily in the recumbent posture, in the sitting, and in the erect postures, also after a brisk trot, and I found the rise to correspond to that of a healthy man. In idiotcy the pulse does not increase proportionately in mania, and in dementia it increases in greater degree. In suspected malingering I have never been deceived by applying this test of the pulse and getting my subject to run a short distance when, if he should be really ill, the rise in the pulse would indicate it.

Butchal Shah was brought up for trial before Judge G——s, at Hydrabad, in October, 1870. His defence was gone into, and many witnesses were produced on his behalf, who swore he suffered frequently from attacks of insanity. The foregoing is the matter of the evidence I adduced on the occasion, and the opinion that I gave was that the man was sane, and had been so when he committed the crimes.

This opinion was corroborated by Dr. N——n, who arrived at the same conclusion by a different process, I believe, and neither of us informed the other previous to our depositions, and we had the gratification when our evidences were concluded, and the trial had lasted several days, all the time previous to which and during which the dissimulation was very cleverly maintained, of the prisoner Butchal Shah throwing off the mask and confessing his guilt, and his attempt at deception, and within one month the law had one more to its deserts in the Synd high priest of Alyar, Scinde, India.

ON THE USES OF HEMLOCK, IN RELATION WITH THE SCEPTICISM WHICH NOW PREVAILS OF THE VALUE OF DRUGS(a).

By Henry Kennedy, M.B., F.K.Q.C.P.,

Physician to Sir Patrick Dun's Hospital, and late Physician to Cork Street, Fever Hospital.

No one, who looks about him on the state of the Profession at the present day, can fail to observe the great amount of scepticism which prevails, as regards the effects of medicines; and this is particularly remarkable in London; where some of the heads of the Profession have not hesitated to publish their opinions on the matter, and strive constantly to teach the doctrine that diseases run their course, quite independent of the treatment adopted, or the drugs prescribed. Some, too, tell us that drugs often seem to cure a disease, when in reality it is the latter which has declined. In fact, the whole amounts to this, that it is the duty of the physician simply to watch the disease; inasmuch as his drugs are useless, and can only interfere with the natural processes of diseases, which, according to these gentlemen, have all, or the greater part of them, a tendency to cure themselves. I must say in my observation of disease I have not found this to be the fact. By far the majority of diseases will go on and on, and persist day after day, till frequently the health of the individual becomes seriously impaired. This, I think, may be safely asserted of all chronic diseases. Witness indigestion in its protean forms, and all it brings in its train; or diseases of the skin, or that disease so common in this country, and which presents such endless variety; I mean chronic rheumatism. Am I wrong in asserting that Nature does not cure any of these affections, or if the disease wear itself out, the patient is worn out with it? But it is in acute diseases, some one will say, that Nature cures the disease; and here it must be admitted there is some truth in the statement; for if the affection be of that character that does not entail organic changes, of which the specific fevers may be given as examples, then, indeed, with our present knowledge, our power of shortening the disease is little, if any. But where an acute affection engenders organic changes, I say decidedly we have a controlling power, by which the attack is shortened, and health restored. As examples, I might mention inflammations of any of the serous membranes, or glandular viscera, or even that disease which is so persistently held up as a type of what Nature can do in effecting a cure; I mean pneumonia. Here it has been so frequently asserted that this disease need only be left to itself, and it will then get well, that it seems to have been assumed as true. Yet I must say without fear of contradiction, this is not the fact; at least it does not square with my own experience. I have notes of a large number of cases where this disease had existed for two, three, and four weeks, without having had any treatment, and yet Nature had not cured them; and even in milder cases where certain changes, tending towards a cure, had taken place, the cure was anything but perfect, and there was still left a linking fire which it only required the smallest spark to light up again. I am much mistaken if what I have just stated be not the experience of others on this point. Similar remarks, too, might be made about acute rheumatic fever, the course of which, according to some of the London physicians, when left to itself is only eleven days. I can only say the disease, as it has come under my own notice in Dublin, is different. For, like the last disease, I have notes of a number of cases which had gone on for more than a fortnight, and yet were so far from having got well that they were then forced to come into hospital, and it may be observed in passing that the very nature of the disease was such as to compel these patients to keep their beds all the time, so that as far as rest was concerned they had it. This part of my subject might be pursued very much further, but I cannot do so here.

From the general tenor of what has preceded, it may be inferred that I am utterly opposed to the scepticism to which allusion has been made, and that on the contrary I have the strongest faith in the efficacy of drugs and Medical treatment. No one, however, is more aware than myself of the many difficulties which surround the study of therapeutics, or the mistakes into which we may inadvertently fall. Still I believe with ordinary caution and prudence, and a slow process of inductive reasoning, we may arrive at such a degree of certainty as the nature of the subject admits, and that the virtues of any drug can, by this means, be ascertained. I have made use of the expression "such a degree of certainty," intentionally. For it requires very little reflection to see that certainty is out of the question. But having spoken of this point on another occasion, I will not dwell on it longer here.

And now to come to the more immediate object of these remarks. In a paper published in a number of the *Practitioner* of last year, on "the present state of therapeutics," I took occasion to allude to the fact that the doses of many medicines had materially altered since they were formerly used; that at present the doses were too small, and that as a consequence these drugs had fallen into disrepute, and therapeutics, as an art, had thus received a severe shock. Of the truth of this statement I have not the slightest doubt, and I shall now endeavour to prove it, by bringing under your notice a medicine which formerly held the very highest repute—then fell into disuse—and only very recently has been again employed. I speak of the famous hemlock, which was so largely used more than a century since. That it possesses all the virtues which were then attributed to it, I do not for a moment suppose. But that it is a drug possessed of great powers, I cannot doubt. It seems to act as a general restorative, and when the proper dose is reached, and this is a matter of more difficulty that might be supposed, the patient begins at once to improve. They gain flesh and even colour, and so the disease is cured (a). If, however, we wish to get its full effects, I agree with Harley, that it must be given in what he calls the physiological dose. He seems chiefly to have used the succus conii of the British Pharmacopœia, and a very elegant preparation it is; but it has this objection, and more particularly with children, that one third part is spirit. To avoid this, I have latterly been in the habit of directing the extract made into a mixture, and by a very little management a very palatable mixture can be made, to which children will rarely object. The flavour of the hemlock itself is not, however, by any means unpleasant, being very like indeed to that of liquorice ball. It is but right to say that with some few individuals, but they are very exceptional, I was not able to make the hemlock agree. They said it made them sick, and it had to be given up. Probably the detail of two or three cases will not be out of place, and may give a better idea of the effects of this medicine than any general remarks.

(a) Read before the Surgical Society of Ireland.

(a) This expression reminds me of a statement which it is now the fashion to make to the effect "that the physician cannot cure disease." For myself, I believe he can, even in the strictest sense of the words. But probably it would be better to express it thus—"That the physician treats, and, with the assistance of Nature, cures disease." I think it might be well to call on the opposite party to state what diseases—excepting those of the malignant class—are not curable, or, at the very least, remediable. In place of vague assertions we would then have something definite, with which to grapple.

Case I. (a)—I was asked, in August last, to see a girl 5 years of age. She was pale, and very thin, and her mother said her appetite was at a stand. Within the previous fortnight of my seeing her a gland had begun to enlarge under the right ear, and when I first visited her was larger than a walnut, and so painful that the child kept her head quite fixed, and was unable to turn it in any way, much less to let the tumour be touched. I must say I had the very slightest hopes of being able to prevent suppuration, which would have been so serious in a girl. However, an ointment of hydriodate of potash with extract of belladonna, was ordered to be applied externally, and at the same time a hemlock mixture was given internally, the child getting three grains of the extract three times a day. This was afterwards increased till she was taking seven grains three times a day. The results here were very marked, for literally, within the first two days, the mother observed that the child began to eat, the pain and then the swelling subsided, and at the end of three weeks every sign of the tumour had disappeared, and the little patient had improved to such a degree, both in looks and flesh, that it was hard to recognise her as the same child. I know not whether others have met the same difficulties as I have myself in the treatment of cases similar to this one. But I do know that in my own hands they have been very obstinate and most tedious, and too often have gone on to suppuration, and even when they did get, in a degree, well, the process occupied months and not weeks, as in this instance. I shall be very glad to hear any remarks on this subject. It is to be observed that this child took twenty-one grains each day of the extract, which by some might be thought to be too large a dose. But it did not prove so.

Case II.—A young lady of ten years of age, began to cough. At first it did not attract any particular notice, and some months passed over, during which the cough continued, at times a shade better, and then worse again. During this period there was a very gradual loss of flesh, and a change in the girl's habits. From being very stirring and active she became listless and easily tired, and she now complained of pain in the chest each time she coughed. She also had some night sweats. In this state she was brought up to town, and was seen by Dr. Hudson, and myself. After the closest examination we could not detect any positive physical sign of tubercles, but there was bronchitis particularly to be heard in the upper lobes of the lungs, and only on a forced inspiration, nor had we any doubt but that tubercular phthisis threatened. Besides other measures, change of air was advised, for she lived in the west of Ireland. But as it happened that this measure could not be carried out at once, it was agreed to put her on a course of the hemlock, and she was directed to take one drachm of the succus conii three times a day. After three weeks, during which she was at home, a marked change for the better had occurred; the cough had lessened, and did not hurt her so much, and in every other way she had improved, and when brought a second time to Dublin, there could be no question whatever of her improved state. After spending some weeks in Wales, this patient returned in perfect health.

Case III.—A boy of 9 years of age, was brought to me by his mother. He looked a strong healthy boy, nearly as broad as he was long, and was what would be thought fat. For more than a fortnight he had been suffering from pain in passing water. At first he only complained of it occasionally, but the last few days it became much more constant and severe, and the boy had got into the habit of dragging the prepuce almost constantly. On looking at the penis the prepuce was somewhat swollen, and there was a slight discharge from the urethra. His tongue was slightly furred, but there was no loss of appetite. He was directed two doses of an alterative aperient, and then he was put on half drachm doses of the succus conii three times a day, and this was increased, on the third day, to a drachm. Under this plan the boy got quite well in a fortnight. I have detailed this case because it is one of by no means unfrequent occurrence, and because cases of a similar kind often give rise to the question of the presence of a stone. Indeed, I have known instances of this kind, and probably I address many who have also met them. I believe the great majority of all these cases have no stone in the first instance, even though all the symptoms of a calculus be present. I know not if any present may recollect a case brought before this Society by the late Dr. Bellingham, in which a very great difference of opinion existed as to the presence or not of a stone in the bladder of a boy. It was suggested to try Medical treatment, and under it all the symptoms of stone disappeared. The boy remained perfectly well for, I think, two years, when symptoms of stone again recurred, and finally one was successfully removed by lithotomy. I repeat that this class of cases presents often examples of great practical interest to both the physician and the surgeon, and I shall be glad to hear the remarks of any member on this point.

Though I have given the hemlock in a number of other instances, and in the great majority with marked success, I will not detain the meeting by giving any more of the details. Suffice it to say that I have given it in a number of cases of chronic disease of the lungs, such as phthisis, and asthma, with chronic bronchitis, and though nothing of a cure was to be expected in such cases, yet it was remarkable how much the greater number were benefited; indeed, so much as to be able to leave the hospital in a very short time. In many cases of neuralgia the hemlock will cure the disease, but not in all. One case of the greatest intensity came under my care in August last year. The disease attacked one side of the face, and was so severe and had so long continued, some years, indeed, that the man's features were quite distorted. In this instance every remedy failed in my hands, including hemlock and electricity. Finally, in Steevens's hospital, Dr. Robert McDonnell divided the nerve close to the ramus of the lower jaw. But I believe it had no influence on this terrible disease. I have only had one instance of chorea under my care lately. The patient was a boy 10 years of age, in whom choreic symptoms set in very shortly after he got a great fright. The disease affected only the right side of the body, but this it did severely the boy being quite unable to feed or dress himself, and the grasp of the hand being much weaker than that of the left. His speech was but slightly affected. The beat of the heart was much stronger than natural, in fact it was excited, and there existed a well-marked soufflet, occupying the first sound, and particularly audible between the left scapula and the spine. In this case I made use of the hemlock, but I was much longer in reaching the proper dose than was needed. This arose from the caution which was used. But I believe I am now in a position to say that children will bear hemlock, as they do belladonna, that is in much larger doses in proportion than adults—a fact of no little importance to establish—but which yet, it must be allowed, affords a wide field for investigation. The boy of whom I have just spoken, got finally eleven grains of the extract of hemlock, three times a day; under which dose the disease rapidly subsided, and the soufflet with it. Whether this drug will ultimately be found a good remedy for chorea, I will not take on me to say, but I believe it is very likely to prove useful.

In the cases where hemlock was used, it is but right to state, that it was given, as far as possible, by itself. Cases, however, did occur when other medicines, such as iron, bromide of potassium, were joined with it, as the indications for the latter were very obvious, and I did not think myself justified in keeping to the hemlock alone. On this point of giving a medicine by itself we cannot be too precise, for it is truly wonderful what mistakes are made about it, and it need not be added that no precision in therapeutics can be reached without it. I have read of particular drugs being given for a disease, and on coming to enquire into the matter have found two, three, and even four medicines were in the one recipe.

In prescribing, too, any drug, hemlock amongst the rest, it is always of consequence to say what preparation is used.

(a) This case was seen by Dr. Montgomery, of Blessington Street.

For in spite of every care in the preparation it admits of no doubt that they vary in quality and strength. When hemlock came into vogue more than a century ago, I mean in Germany, its fame spread with great rapidity, and yet it seemed to have as rapidly fallen into disrepute, and it was asserted by many that it had quite disappointed them. Need I add how common an occurrence this has been with many other drugs? Now I cannot doubt that this is partly to be explained because the same attention was not given to those details which are absolutely essential in prescribing a drug of this nature, and which are all described by the writers of the time of which I speak. It would not be possible to enter into these details here. Suffice it to say they relate to the mode of growth, being in the sun or the shade, to the season of the year, to the particular portion of the plant used, to the best mode of preparing and keeping it, and, above all, to the dose to be given. I do believe that the latter point is of all the most important, and yet it is only some five years since, in fact, Harley took up the subject, that we are again begining to recognise its importance, and it is the point which I wish more particularly to bring under your notice this evening. That the hemlock is constantly ordered in doses which are utterly futile I cannot doubt, and some, indeed, go even farther than this, for very recently I was asked had I any faith in it at all. With such views on the matter, it is easy to understand why hemlock has fallen into disuse, and the same remark may, indeed, be made of many other most valuable drugs. In answer to all such views, I have only to say that hemlock will be found a safe and valuable restorer of the general health, and applicable to a number of diseases, especially of the chronic class. But then it must be given in the proper doses, which are much larger than those in common use, and the views so clearly laid down by Harley must never be forgotten. That from various causes, and from the necessity which always exists for using a prudent caution, some little difficulty may exist in reaching the proper dose, I am free to admit. A difficulty of this sort, however, only requires to be noticed in order that it may be met.

In conclusion, I have only to state that the doses of the several preparations of hemlock, as given in the British Pharmacopœia, are much too small.

◆

American Communications,

[We open this New Department of the Medical Press in order to afford our numerous American supporters a medium for communicating their views to Europe. Articles intended for this purpose should be written expressely for us, as it is not intended *in this Department* to reproduce contributions to our American contemporaries. They are noticed or cited in another column. Subjects of special interest to America and Europe are appropriate. Dr. Nathan Allen's high practice and life-long study of social and physiological problems, render it particularly gratifying to us to open the Department with an article from his pen.—Ed. Med. Press.]

THE TRUE LAW OF POPULATION, BASED ON PHYSIOLOGY AND PSYCHOLOGY.

By Nathan Allen, M.D.,

United States Commissioner at the late European Congress on the Treatment of Criminals, the Prison Laws, &c.

It may appear almost presumptuous to assume the phrase, "true law," which might seem to imply that all other theories were false or not true; but such is not our meaning. It is intended to express this sentiment, that whatever views are entertained on this subject, or however diverse they are, they must all, as far as true, be subservient to a great general law which has its origin and foundation in physiology.

More than thirty years ago, a work was published in London with this title, "The True Law of Population shown to be connected with the Food of the People." The merits of this work consisted very much in the evidences which physiology afforded in support of its theory, arising from the effects that food combined with other agencies had in changing physical organisation. But, unfortunately, Mr. Doubleday, the author of this work as well as some other writers upon population, have not been thoroughly educated in the principles of this science.

As this subject is so vast and complicated, a large volume would be required to discuss it properly, especially in expounding any new views; we can present here only a few points of heads of topics, by way of suggestion and illustration. An examination into the views and theories of most writers upon population shows that the laws which they lay down for its increase have been controlled generally by agents or objects entirely external to the body, and some of them hold only remote or indirect relations to it. Now, while these external agents, such as food, climate, exercise, &c., may operate as powerful factors or as secondary causes, we maintain that there is a great general law of propagation which extends through the whole animal and vegetable kingdoms. Whatever influences these agencies may have in the development of the body, the most important agent or law of all, the law that shapes its life, character, and destiny, it would seem, must have its origin and seat somewhere in the body itself. What then is this Law? It may be defined thus:—*It consists in the perfectionism of structure and harmony of function*; or in other words, that every organ in the body should be perfect in its structure, and that each should perform its legitimate functions in harmony with all others.

While this perfect physical organisation is nowhere to be found in nature, we can readily conceive of such a standard, and that there may be all manner of approximations towards it. The nearer this standard is reached, the more complete, the law of propagation can be carried out. This theory is supported by evidences deduced from physiology in a variety of ways.

All diseases interfere with the operation of this law, especially those that are considered hereditary. This class of diseases become intensified by each generation and tend rapidly not only to impair the vitality, but to blot out the existence of the race. There is another class of diseases or weaknesses, described under "sterility," "barrenness," and "impotence," from which strong evidences may be derived.

There is a general principle in physiology, favourable to this theory, which is thus described by Dr. Carpenter:—"There is a certain antagonism between the nutritive and reproductive functions, the one being exercised at the expense of the other. The reproductive apparatus derives the materials of its operations through the nutritive system and its functions. If, therefore, it is in a state of excessive activity, it will necessarily draw off from the individual fabric some portion of aliment destined for its maintenance. It may be universally observed that when the nutritive functions are particularly active in supporting the individual, the reproductive system is undeveloped and *vice versâ*." Let, therefore, any class of organs or any parts of the body be unduly or excessively exercised, and it requires the more nutrition to support them, thereby withdrawing what should go to other organs. In accordance with this physiological law, if any class of organs become predominant in their development, if what may properly be denominated one of the temperaments becomes excessively developed, it conflicts with this great law of increase. In other words, if the organisation is carried by successive generations to an extreme—that is to a high nervous temperament—a predominance of the brain and nervous system; or on the other hand, to a sympathetic temperament—a predominance of the mere animal nature, it operates unfavourably upon the increase of progeny. Accordingly in the highest states of refinement, culture, and civilisation of a people, the tendency has always been to run out in offspring; while on the other hand all tribes or races sunk in the lowest stages of barbarism, controlled principally by their animal nature, do not abound in offspring, and, in the course of time, they tend also to run out.

The same general fact has been observed among all the abnormal classes, such as idiots, cretins, the insane, the deaf and dumb, and, to some extent, with extreme or abnormal organisations, such as are excessively corpulent, or spare, as well as of unnatural size, either very large, or diminutively small.

A similar fact has been observed among distinct classes, such as the nobility, the aristocracy, &c., where by inheritance, refinement, and culture the nervous temperament becomes very predominant; it is found that such families in the course of a few generations do not increase in offspring, and, not unfrequently, in time, they become extinct.

A similar result has also followed the intermarriage of relations, from the fact, that the same weaknesses or predispositions are intensified by this relation. Again, if we take those familes and races which, for successive generations, have steadily increased most, we shall find, that, as a whole, they possess a remarkably healthy, well-balanced organisaton. Illustrations of this type, we shall find, abound most among the middling or working classes of the German, the English, the Scotch, the Irish, and Americans.

The laws of hereditary descent afford strong evidence in favour of some general law of propagation. The fact, that "like begets like," subject to certain variations and conditions, is a proverb that has been too well attested to be called in question. The union of two agents, possessing similar and dissimilar qualities, constitutes an important condition to which this law of propagation is subject. While it may be difficult to point out, in all cases, the exact results of hereditary influences, still it has been found on a large scale that, in the aggregate, there was the most unquestioned evidence of such agency, and that it was minute and extensive, and continued for successive generations. When this department of physiology becomes thoroughly understood, hereditary influences will more readily be traced back to their primary sources and to the secondary causes operating to change and modify them. Now the same evidence that proves the existence of hereditary agency, implies that there is somewhere a general law, of which this is only part and parcel; and no one thing will throw so much light upon this whole subject of inheritance, as the recognition of a law of propagation, being based upon a perfect standard in nature. Again, there must exist in physiology a certain standard or type of organisation for woman, best adapted for increase both for herself and her offspring. This, we believe, consists in a perfectly healthy and well-balanced body, that, with such an organisation, the pregnant state harmonises, the process of delivery is the safest, and the materials for nursing offspring are found most complete.

This theory of human increase derives evidence from an analogous law in the animal and vegetable kingdoms. It is well known that wonderful improvements have been made, within the present century, in domestic animals, and this chiefly too, by an application of physiological laws. To such an extent have the results of of observation and experiment been here carried that this process of improvement has been reduced almost to a science. The terms here used, "Pure Blood," "Thorough-Bred," "Pedigree," "Breeding in-and-in," and "Cross-breeding," may all be explained by two great leading principles. One is a general law of propagation based upon a perfect standard, and the other is, the law of inheritance subject to certain conditions.

In fact, these two laws constitute, we believe, the two great principles that underlie most of the theories of Charles Darwin; these are discussed under the head of "Natural Selection," and the "Law of Variability;" and whatever may be said against his theories, of the "Origin of Specie," and "Descent of Man," these two general principles are in our opinion founded in nature and will survive all opposition and criticism.

A similar law of propagation exists in vegetable physiology. It is a fact well attested by Gardner, that in order to produce flowers and fruit, the soil must not be too rich or too poor; if the plant or tree grows too luxuriously, its branches or roots must be pruned; while on the other hand, if unthrifty, it must receive better culture and its roots be enriched before it will become fruitful. So the most beautiful flowers and richest fruit have few seeds, which in time run out, while that of a poor quality may abound in seed, but will not flourish long. It is true the conditions here vary, and so do the modes of perpetuating life; but, by analogy, facts and arguments of a positive character may be gleaned from this source to confirm a similar law in human physiology. Other facts and arguments might be adduced in favour of such a theory of population, did time and space permit, but we close with two or three suggestions. If this law of propagation is true, it presents a great standard for improvement, where there may be found the perfect free agency of man, and, at the same time, the highest motives for improvement. It could not have been intended by the Creator that man should always be ignorant of, or ignore the great law of propagation in many respects the most important in the universe; neither could it have been intended that man as a moral and accountable being should be a mere *passive agent* in the propagation of the species.

Again, this law of population should interest Medical men, as it affords a new stand-point in physiology to study the relations of the body as a whole and especially in their connection with the reproductive organs, which have constituted the chief study on this subject. It presents also in some respects, a new guide to female organisation as to what is the normal or best standard for the propagation of the species, and it may throw light on the changes occasioned by pregnancy, as well as on the qualities indispensable for good nursing. It explains in a clearer light than ever not only the laws of hereditary descent, but magnifies their value and importance in relation to human progress and welfare. It opens new views connected with anthropology, and aids in explaining many changes in the history of different races and nations. Inasmuch as it furnishes a new key to the study of the body, and exalts physical laws in their connection with human improvement, it should certainly interest Medical men. From more than thirty years of observation and experience in a busy professional life we have become every year convinced more and more of the truth and importance of the law here so briefly discussed, and would commend it to the attention of all enquirers after truth in this great field of observation and study.

Lowell, Massachusetts, U.S., January, 1873.

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

Monday, 13th January, 1873.

Thomas Bryant, Esq., F.R.C.S., President, in the Chair.

Dr. Thorowgood read some notes of a

FATAL CASE OF INTESTINAL OBSTRUCTION.

M. C., æt. 60, was seen by Dr. Thorowgood on the evening of Monday, May 20, 1872, with Dr. Wallace, of Hackney. The general health had been good up to five weeks previous, and on the 16th May he was seized with severe pains of a griping and twisting character. The bowels had been for several days without action; frequent enemata and purgatives failed to give any relief; recourse was had to opium, which relieved the pain. When seen on the 20th of May he had been a week without an action of the bowels, his face was flushed, pulse 88, not thready; tongue dry; frequent vomiting, but not of a stercoraceous nature; no jaundice; no passage of blood by bowels. Abdomen swelled and tense; a solid mass felt on right side.

A large injection was given by means of the gravitation tube; it passed easily into the bowel, and returned, bringing with it a few small pellets of fæcal matter. An ointment of mercury and belladonna was applied over the abdomen, and quarter-grain doses of ext. belladonna were given every two hours. Seen again on the 24th. Tongue quite dry; pulse 88; urine scanty and turbid, and distress extreme. An injection containing extract of belladonna was given, and a pill as follows:—

℞ Pulv. opii. gr. ¼.;
Ext. belladonna, gr. ¼.;
Plumbi. acetatis, gr. ss.

Every two hours. After he had taken about ten pills the bowels acted freely with immense relief. On the 30th May he had four good consistent motions, and the mass on the right side got much smaller.

June 6th.—The obstruction appeared again with stercoraceous vomiting; for a time he got some relief by taking pills of aloes grip three times a day, and the mass on the right side became scarcely perceptible, the bowels acting with loose motions under the influence of these pills.

Aug. 3.—He sunk and died quietly. The post-mortem was made the next day by Dr. Wallace, who was allowed to examine the abdomen only; the only morbid appearance found was extensive atheroma of the aorta and iliac arteries. No stricture or tumour was found involving the bowel through the lower part of the small, and the whole of the large intestine was carefully examined. The coat of the large intestine was wasted and thinned to a great degree. In commenting on this case Dr. Thorowgood alluded to the importance of careful diagnosis, the rectum especially should be examined by the finger, and by a bougie or tube, to see if there be present one of those annular strictures high up which were described by Mr. Henry Smith in his Lettsomian Lectures in 1865.

The intense twisting pain at first seemed to point to a possible intersusception as the commencement of the trouble. To relieve this belladonna was tried, and this not succeeding, acetate of lead was added in the hope that as lead acts powerfully on the muscular coat of the bowel, so as to alter its calibre, it might in some way aid to untwist the invagination. One case was mentioned in which acetate of lead given thus had succeeded in affording relief, and in the present case after as much as five grains of the acetate had been given, copious relief followed. The bowels having been once opened, attempts were made to keep them open by enemata and stimulating purgatives: and though these succeeded as far as to remove the swelling on the right side of the abdomen, yet the patient sunk and died with all the symptoms during life and appearances after death of atony and wasting of the bowel. In reply to questions by Mr. de Meric and Dr. Wiltshire, Dr. Thorowgood thought latterly in the case galvanism after the method advised by Dr. Althaus might have been used with benefit. He did not himself see the patient later than June, but did not think galvanism was used during life. There was no evidence of heart disease. The mesenteric arteries were not examined, and Dr. Thorowgood had no theory to offer as to any causal connection of the atheroma of the aorta and iliacs with the atony of the bowel. In reply to Dr. C. T. Williams, Dr. Thorowgood said he gave the acetate of lead when all other means had failed, in the hope that it might by acting on the muscular coat of the stomach untwist the invagination; further, he had known the acetate of lead given in one case with conspicuous success. Dr. Wiltshire asked whether electricity would not have been useful? He cordially approved of treatment by means of opium and belladonna, but would not nux vomica or strychnine have been very useful in this case? He also asked whether there was any disease or plugging of the mesenteric arteries, especially of the parts of the bowels which were found to be thinned? What had become of the tumour felt during life? Was it a fæcal tumour due to paresis of the damaged bowel?

The **President** said many old people died from bowel disease, especially fæcal obstruction of the lower bowel. Many so-called cancer cases were of this kind. The intestine seemed to die first. He thought stimulating enemata were more useful, and he had seen striking results from electricity. Were there not cases of obstinate constipation which justified opening the abdomen? He related a case of a severe kind in which colotomy was performed, the cæcum being opened and found to be empty. Afterwards some fæcal matter followed, and the patient got well with an artificial anus. Four years afterwards the wound was closed, the lower bowel having been prepared for some days previously by injections. Such a case showed that circumstances did sometimes arise which justified operation in cases of severe and prolonged constipation.

Dr. C. **Theodore Williams** then read a paper on

THE VARIOUS MODES OF CONTRACTION OF CAVITIES IN PHTHISIS AND THEIR RESULTS.

The author commenced by observing that it was very difficult to foretell contraction of cavities, and remarked that when it took place the patient was by no means out of harm's way, for the contractile process might overstep the required bounds, and seriously obstruct respiration and circulation, causing death by dyspnœa and dropsy. Moreover, fresh diseases might arise in the other lung. Contraction of cavities, according to Dr. Williams's statistics of 1,000 cases, occurred in six per cent. of patients in the third stage, and the void was filled in by one or other of the following means:—1st. By expansion of lung tissue around the cicatrix. 2nd. By an expansion and drawing over of the opposite lung to the affected side. 3rd. By displacement of the neighbouring organs, the heart, liver, stomach, and spleen. 4th. By collapse of the chest-walls. Dr. Williams then dwelt upon these modes of compensation, and explained the changes which the physical signs undergo during contraction, especially the increase of resonance over the former seat of the cavity and the shifting of the cavernous sounds to the posterior regions of the chest previous to their disappearance. This was owing to contraction always taking place towards a fixed point, which was generally the root of the lung, but not necessarily so, as it might be some spot where the pleura was strongly adherent. A contracting cavity of the left lung, as a rule, caused more displacement of organs than one of the right. When the cavity was in the right lung, the liver might be raised, the left lung drawn across and the heart considerably displaced upwards, outwards, and in the direction of the axillary region, which it sometimes reached. Collapse of the chest-wall generally took place in all cases of contracted cavity, but often at a late date, the expansion of the healthy lung and the displacement of organs, particularly the abdominal, sufficing to fill the void for some time. Several cases were given to illustrate these points. The author then drew attention to the various periods required for contraction of a cavity in these cases. In some it took place in two months, in others it occupied two years, the size of the cavity being no index of its rate of contraction. The results of the process on the general health of the patient was then considered, and it was pointed out that in some patients the contractile process caused so much obstruction to the respiration and circulation as to create great and increasing dyspnœa, irregular action of the heart, and eventually death. Another termination was by albuminuria (dropsy), and the few kidneys examined after death showed signs of degeneration.

Dr. **Thorowgood** agreed with Dr. Williams that more attention ought to be paid to the phenomena of contraction of cavities. He thought it occasionally followed symptoms of inflammatory action. He would like to hear more as to the best means of promoting the contraction of a lung cavity.

Dr. **Sansom**'s experience went with Dr. Thorowgood, that contraction often followed evidence of local irritation, and he thought perhaps it might be well to induce such a process. Acupuncture might possibly be justifiable.

Dr. **Williams**, in reply, said he knew of no means of promoting contraction of cavities, but he had found endeavouring to improve the patient's health and strength and allaying local irritation to be the best course to pursue. He could not agree with Dr. Sansom that the induction of a state of hyperæmia was advisable, and he should hesitate about the use of acupuncture of the lung, although Dr. Dieulafoy had shown it to be less dangerous than was supposed with regard to cavities, being more likely to contract in one kind of phthisis than in another. His impression was that this was the case in phthisis of pleuro-pneumonic origin. He had not found that intercurrent inflammation assisted the contractile process, but rather the reverse.

DUBLIN PATHOLOGICAL SOCIETY.

THE usual weekly meeting was held on Saturday, Feb 1.

The President, Dr. KIDD, in the chair.

Mr. HAMILTON said he desired to lay before the Society a case of

FRACTURE OF THE CRANIUM,

which possessed a certain amount of pathological interest, owing to the great disproportion which existed as to the outward evidences of injury and the amount of injury met with after death. The subject of the case before them was a boy, aged eleven years, who, in the act of opening a double gate, having opened one side of it, was endeavouring to open the other, when the first portion suddenly slapped upon him, and compressed his head between it and the other leaf of the gate. He immediately fell down insensible, and was conveyed to Stevens' Hospital, where he was seen by him (Mr. Hamilton) soon after admission. He was then in a state of collapse, having a cold clammy skin, the pulse being at 58. He presented an extensive contused and lacerated wound over the left temple, extending back towards the myatis. On introducing the forefinger into the wound, there was distinct evidence of a depressed fracture of the skull, and small portions of the bone apparently detached could be felt. As the boy suffered a great deal by collapse, and as the bone was felt to be depressed, and had it exposed as it were in an open wound, it was considered desirable to *dilate* the wound, and endeavour to raise up the portion of bone that was depressed. The patient showed distinct evidences of pain; he plainly appreciated the pain caused by any attempts to examine the wound, and also by the operative processes which were considered necessary. The most striking feature in the case was, that while they had undoubtedly the depression in theory, they had certainly not the symptoms that were attributed to compression of brain. That there was compression of the brain was beyond all doubt—it could be seen and felt; and yet they had no dilated pupil, no stertor, no whiffling breathing, no paralysis, no convulsions; and it was the mere fact of their having been able to feel the depressed bones that induced them to adopt means to reduce portion of the bone. The boy was placed in bed, and after some time he was able to partake of stimulants to a moderate extent. He continued in that state in the evening, and towards the latter part of the night; but in the morning he recovered a certain amount of consciousness. On the following day he rallied somewhat, his pulse had risen, and his powers of swallowing had returned. He distinctly manifested consciousness, and was perfectly sensitive as to pain. He occasionally spoke, but it was not easy to make him answer intelligently. He continued in that state until nine o'clock on the Thursday following, when he got very restless and uneasy, tossing himself about to such an extent that it was difficult to keep him in bed. His pulse ran up to between 140 and 150, and about eight o'clock on the following Thursday morning he died. On examining the skull, considerable depression of a large portion of the cranium was discovered, a portion of the bone compressing the frontal, temporal, and parietal bones which had been pressed down to such a degree that considerable injury to the surface of the brain was found to have been inflicted, and a portion of its substance exuded. Considerable interest was manifested in the case, and the result of the examination showed that the injury was depression of bone. The case as a mere fracture of the skull had not much pathological interest, but it was of interest showing that they might have serious mischief done to the brain if these symptoms laid down in books could not be found to be present.

ACUTE PNEUMONIA AND CIRRHOSIS OF THE LUNG SIMULATING GANGRENE.

Dr. NIXON exhibited the heart and lungs which were taken from the body of a woman, aged thirty, admitted under his care into the Mater Misericordiæ Hospital on the 23rd ult. The history of her illness, obtained by the resident pupil from herself, was briefly as follows:—A week before admission she got a severe wetting, followed by a shivering fit and great prostration. She was treated for bronchitis, but experiencing no relief, she presented herself at hospital. She was the mother of seven children, enjoyed good health up to the time of her present attack, never suffered from cough, and never spat blood. When he saw her on the morning of the 23rd ult. she was in a dying state; the extremities were cold; she was almost pulseless; the radial beats were so flickering and irregular he could not count them; the face was sweating, and extremely pallid; the respirations were rapid, but very feeble; there was an intolerable stench from the breath. On a hurried examination (the state of the patient precluded a long one), he found evidences of pneumonia in the right lung, both in front and behind. Posteriorly corresponding to the base of the left lung marked dulness existed on percussion; and, on stethoscopic examination, a very loud coarse mucous râle could be heard—it accompanied both inspiration and expiration. There was no expectoration at the time he examined the patient, so he could not state its nature. The heart was examined by Mr. Brown, the Assistant Physician of the Hospital, previous to admission. Its sounds were entirely masked by the respiratory murmurs. Taking into consideration the history of the case, the rapid prostration, the physical signs which existed, especially those detected at base of left lung, coupled with the intolerable fœtor of the breath, he was led to believe that the case was one of double pneumonia, and that the inflammatory action had run into gangrene. The woman died about twelve hours after examination. The *post-mortem* was made by the resident pupil, Mr. Rice. The lungs might be said to be non-adherent; there was a very slight difficulty in removing the lower part of left one. The bronchial tubes presented evidences of recent inflammation. The upper lobe of the right lung was in the third stage of pneumonia; its texture was in parts soft, and almost diffluent. The lower lobe of the left lung presented a remarkably small and atrophic appearance. The pleura and sub-pleural tissue covering it was much thickened, and evidently the seat of fibrous deposition. In a section made through the centre of the lobe a distinctly dilated bronchial tube was visible. A portion of the lobe which he injected with white wax gave exactly the appearance of an advanced case of cirrhosed liver. It was in that condition originally described by Sir Dominic Corrigan as "cirrhosis of the lung." There were no tubercles in either lung. In the heart he found the right cavities dilated; both left chambers were also dilated. The walls of left auricle were hypertrophied; those of left ventricle somewhat thinner at the base than the normal size. The edges of both flaps of mitral valve were thickened and adherent, producing mitral stenosis and incompetency (a). On the surface there was a large deposition of fat. The microscopic examination of its muscular fibres showed plainly the transverse striæ, but here and there traversing the fibres were seen little longitudinal beads of granules. The condition observed was similar to that produced in what is known as "brown atrophy of the heart." The points which induced him to bring the specimens before the Society were—Firstly. The existence of advanced chronic disease in one lung and in the heart without manifestation of any distressing symptoms during life prior to last illness. Secondly. The probable connection between the diseased state of the heart and the sclerosis of the lung; the mechanical impediment to the circulation leading to congestion, exudation, and proliferation of tissue. Thirdly. The absence of tubercle in the lung as local cause of the diseased condition found. And fourthly. The intolerable fœtor which existed, and which, with the physical signs at the base of the left lung, led him to believe the inflammatory process had terminated in gangrene. The fœtor must have depended on the retention in the dilated bronchi of the secretion of the inflamed mucous membrane which underwent decomposition.

PERFORATING IDIOPATHIC ULCER OF THE ŒSOPHAGUS.

Dr. HAWTREY BENSON exhibited a specimen which he had removed from the body of a woman who died in the City of Dublin Hospital. She was aged fifty, but on admission she had all the appearance of seventy-five or eighty. She was extremely emaciated, and had much of that peculiar cachectic appearance which would lead one to say she was the victim of cancer somewhere; at the same time, the glands in the neck and groins, and axillæ were greatly enlarged, and those of the mesentery could be distinctly felt to be hypertrophied through the attenuated walls of the abdomen. She complained of slight "soreness," referred to the sternum; but by far the most prominent symptom was extreme dysphagia. Whenever she attempted to swallow anything it invariably regurgitated. From this fact, taken in connection with the enlarged glands, and the appearance of the patient, Dr. Hawtrey Benson was led to express an opinion that he should eventually find cancerous disease involving the œsophagus, and obstructing the passage of food. Owing to the extreme dysphagia, Dr. Hawtrey Benson was compelled to introduce nourishment by the rectum. This he continued for three weeks, till the patient astonished him by gradually regaining the power of swallowing, so that very soon she performed deglutition with ease, and she rapidly improved. Dr. Hawtrey Benson now modified somewhat the terms of his diagnosis, and thought it more likely that a tumour had been pressing on the œsophagus, and obstructing the passage of food, and that now, from some cause unknown, the tumour had altered its position and no longer obstructed the canal. The improvement that followed this change was not destined to continue long, for after about ten days an incontrollable diarrhœa came on, under which she again emaciated, and gradually sank. At the *post-mortem*:—On opening the abdomen all there was healthy. He then split up the diaphragm and opened the chest, and proceeded to look for the cause of the dysphagia. In doing so he raised the left lung gently, and immediately perceived what proved to be the contents of the stomach discharging itself through an oval opening in the œsophagus, about five inches from its extremity. This opening was an ulcer, which, commencing on the mucous surface of the œsophagus, had perforated all the coats of that organ, even the layer of pleura covering it, and had commenced to attack the apposed pulmonary pleura, as was shown by a circumscribed patch of vascularity on that membrane corresponding in size, shape, and position to the ulcer. A thin layer of lymph must have prevented extravasation during deglutition, but was torn through when the lung was raised out of its position. On slitting up the œsophagus, a patch of ragged ulceration of the mucous membrane was found, about the size of the palm of one's hand, distributed around the central perforating portion. This latter was about the size of a shilling, and had a rounded, thickened margin. Dr. Hawtrey Benson thought that in the state of the parts he had a reasonable explanation of the apparently anomalous symptom of very extreme dysphagia, followed by comparative ease in deglutition; for, while the disease was more recent and the inflammation acute, a reflex spasm of the œsophagus doubtless took place on the introduction of food, which ceased to occur when deep destruction of the tissues was the result, and the inflammation became less acute. The specimen, he thought, afforded an interesting example of a very rare disease, occurring in an organ whose maladies are confessedly so rare and so obscure, of which so little was known before the writings of Hamburger and Oppolzer.

(a) There were slight patches of atheroma at the origin of the aorta.

Dr. Hayden said he had to claim the indulgence of the Society owing to a mistake which had been made by his servant, who had not brought over the right specimen. The one before them was, however, of some interest, and he should briefly detail the circumstances connected with it. The subject was a man, aged 53 years, a gardener, of temperate habits, who had been in hospital two years previously under his (Dr. Hayden's) care for bronchitis and pleuritis of the right side. He was re-admitted into hospital on the 20th January, again suffering from bronchitis, and there was evidence, likewise, of pulmonary emphysema. His pulse was remarkably weak, but regular; but it was what might be called a failing pulse. The action of the heart was likewise exceedingly weak; no impulse was to be felt, and the sounds, which were masked by loud bronchitic râles, were audible only during momentary suspension of breathing at the lower end of the sternum. Here the second sound was all but suppressed, and a loud bellows murmur accompanied the first. This murmur was transmitted about three inches upwards in the course of the aorta, but not into the arteries of the neck. In the interim between his first and second admission to hospital he had suffered from repeated fainting fits, and on one occasion he actually fell down in the street. That fit lasted some four or five minutes, during which time he was quite unconscious; but he afterwards managed to scramble home. While in hospital he had two or three of these attacks, even while in bed. The symptoms he complained of during the continuance of these fits were that his head became quite giddy, his sight dimmed, and he felt as if he were about to die. The fainting fits usually lasted about three or four minutes. The diagnosis he made was,—enlargement of the heart, accompanied by fatty degeneration, and in all probability dilatation and advanced atheromatous degeneration of the aorta. On the 27th February, in one of those fainting fits, the man died in four or five minutes. The lungs were found to be in a very advanced state of emphysematous inflation, the right exhibiting traces of a former but slight pleuritis. The heart was enlarged, weighing eighteen ounces. It was covered at the base and over the sulci and right ventricle with a thick layer of fat. Both ventricles were dilated and hypertrophied, dilatation predominating in the right and hypertrophy in the left. Both contained a large quantity of dark coagulated blood, and their walls were in an advanced state of fatty degeneration, the muscular fibre exhibiting under the microscope groups of oil dots around the nuclei, as noticed by Ormerod and Paget, whilst in most situations no trace of striation existed. The valves were all sound, except those of the aorta, which were opaque, but pliant and competent to close the orifice, and could not have caused a murmur of exit. The orifice itself was in all respects normal. The aorta from above the sinuses throughout the entire arch was greatly but equally dilated, readily admitting the four fingers and thumb; its internal surface was rough, yellow, and in several places fissured through the internal and middle coats, and in one situation a lamina of fibrin, of the diameter of a sixpenny piece, was attached to one of these fissures. The specimen exhibited the not infrequent combination of enlarged and fatty heart, with atheromatous change and dilatation of the aorta. It likewise exemplified a not unusual mode of death in such cases, namely, by syncope. The heart, hypertrophied in compensation of disease of the aorta and subsequently weakened by fatty degeneration of its walls, was no longer able, by its increased power of contraction, to supply the want of elasticity in that vessel; and the left ventricle being entirely emptied of its contents into the greatly dilated aorta, suddenly ceased to contract, owing to failure of arterial circulation in the nerve-centres,—hence the repeated attacks of, and finally the fatal, syncope. Dr. Hayden called attention to the differential diagnosis as between disease at the orifice and in the ascending portion of the arch of the aorta. In the former case the murmur, which is loudest at the orifice, is transmitted throughout the arch and into the great arteries of the neck; but in the latter case, namely, where the walls of the vessel are rough, but the valves and the orifice unaffected, the murmur is limited to the first two or three inches of the aorta, not passing into the neck. He would not venture upon a positive explanation of this difference, but suggested that it might depend upon the circumstance that an axial disturbance of the current of exit, such as would arise from valvular obstruction, might be transmitted to a greater distance in its course than a mere surface ripple produced by a rough state of the coats of the vessel.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JAN. 28TH, 1873.

T. B. CURLING, F.R.S., PRESIDENT, IN THE CHAIR.

A SECOND REPORT ON THE COMMUNICATION OF SYPHILIS IN THE PRACTICE OF VACCINATION.

BY JONATHAN HUTCHINSON, F.R.C.S.,

Senior Surgeon to the London Hospital.

THIS paper contains an account of two series of vaccination-syphilis (each series containing but a single case) which have come under Mr. Hutchinson's notice since his last communication on the subject in 1871. These two cases (forming the author's third and fourth series) are prefaced by a few remarks referring to cases published by others on the continent and at home; the author also re-asserts the great importance of making all such cases public. The latter part of the paper is occupied with general conclusions and recommendations drawn from a consideration of all the cases which have come under Mr. Hutchinson's notice.

THIRD SERIES.—*Case.*—This patient was a respectable small tradesman, forty-six years old, who came under Mr. Hutchinson's care at Moorfields Ophthalmic Hospital with double iritis. Examination disclosed the presence of a copious dusky rash and symmetrical ulcers in the tonsils. The ordinary questions as to syphilis were denied, and careful inspection of the genitals gave an entirely negative result. On one arm, however, two or three scabbed ulcers were found, as large as shillings, with dusky indurated borders; and there was an indolent bubo in the corresponding armpit. He said that the sores on the arm had broken out at the seat of the vaccination-punctures. He had been vaccinated three months before admission; the punctures took, and behaved as usual; but when just healed over, a month after the operation, they inflamed and broke out into sores. About a fortnight later (six weeks after vaccination) the rash appeared, and at the end of another month the iritis set in. The nature of the disease had not hitherto been diagnosed, and no specific treatment had been used; under the use of mercury both iritis and rash were cured. This man was seen by many Medical men at the hospital during the two or three months of his attendance, and there could be no shadow of doubt about the nature of his malady. Although his vaccinator had not diagnosed this man's case, he had had much trouble with the arm-sores, which from subsequent account would appear to have been at one time almost phagedænic. Besides the patient, about twelve others were vaccinated from the same baby, three of them being the patient's children, young adults; in these three no ill results have occurred; the remaining cases have not been pursued further (for prudential reasons detailed in the paper), but the vaccinator believes that none of them had any trouble save one or two in whom a little difficulty occurred in the healing of the vaccination spots. The vaccinator said that the baby used appeared in excellent health at the time. When seen by Mr. Hutchinson at eight months old it was fat and well grown, the only sign of inherited syphilis being the markedly sunken bridge of the nose—a symptom to which the author attaches considerable importance, and from which he predicts with some confidence the future occurrence of confirmatory events. The child was the third and the only living one, the first two having died in infancy. In favour of this man's syphilis having been gained during vaccination we have the occurrence of induration, &c., in the vaccination-scars at exactly the interval which is known from former cases to elapse between inoculation with syphilitic virus and formation of the chancre, the occurrence of axillary indolent bubo, the eruption and other secondary symptoms following the arm-sores at the proper period, and, lastly, the total absence of any trace of chancre elsewhere and the extreme improbability of syphilitic inoculation of the vaccine sores after the vaccination. Against this conclusion there are only the negative facts afforded by the apparent immunity (which may, however, yet be disproved) of the other persons vaccinated, and the slight evidence of syphilis in the vaccinifer: the latter being what is to be expected, since no one would think of vaccinating from an obviously syphilitic child.

FOURTH SERIES.—*Case.*—A lady about forty-five, who came to Mr. Hutchinson as a private patient in December, 1872, for a vascular growth from the urethra. During examination the remains of a copious, dusky, evidently syphilitic rash were found. On inquiry, she stated that she had been very ill after vaccination, and had had a severe rash and inflammation of one eye. Further examination showed the presence of a dusky scar at the seat of one of the vaccination-punctures, very different indeed from a normal vaccine cicatrix; synechiæ were also found in the left eye, proving past iritis. She was vaccinated in May, 1871, by four punctures, none of which took; just a month later one of them inflamed, and became a hard-edged ulcer, lasting three months. Two or three weeks later (about two months after vaccination) the rash appeared copiously, and she fell into ill-health. From the vaccination in May to the early part of September, she had no specific treatment, which probably accounts for the severity of the rash, &c. After this she took small doses of iodide of potassium and birchloride of mercury, under another practitioner, for nine months, when she ceased all treatment, and went for two months to the sea-side. At the end of this period her left eye inflamed (iritis), and the rash, which had been nearly well, relapsed. For the iritis she was treated at Moorfields Hospital by a colleague of Mr. Hutchinson, its cause and origin being suspected, but not followed out. It was several months after her admission to the hospital that she came under the author's care for a complaint having no connexion with the syphilis. She was vaccinated from a baby's arm, and at the same time her two grown-up daughters. A number of others had previously been vaccinated from the same child, but these have not been traced. The two daughters, however, appear to have escaped all contamination. The baby is said by the vaccinator and its own mother to have looked quite well at the time. As soon as dentition began, however, it had some very troublesome sores about the anus (? condylomata), for which it was under treatment three months at a dispensary. It is the third child. All are living. The eldest, a boy about six or seven years old, shows no signs of inherited taint, the second, a girl of five, now has a large forehead, and she had exactly the same sores about the anus and at the same age as the vaccinifer; the vaccinifer itself also now has a large forehead. The author calls attention to the fact that these two cases of vaccination-syphilis were not, as were the first and second series, sent to him because he was known to be interested in the subject, both of them having occurred in the ordinary course of practice. Several cases of supposed syphilis from this cause have been sent to him, but the diagnosis in these was not confirmed.

Conclusions and general remarks based on the four series of cases.—These are summed up chiefly as answers to certain questions. The author first asks:—What are we to infer from the circumstance that when syphilis is conveyed in the practice of vaccination it does not affect all those vaccinated from the tainted source? And he answers: We must believe that the specific poison of syphilis is either not contained in the vaccine lymph at all, or is not equally diffused through it. Thus, in the first series of cases, two out of twelve vaccinated escaped syphilis; in the second series, out of about twenty-six vaccinated more than half escaped; while in the third and fourth series only one out of at least twelve vaccinated from each vaccinifer is known to have been syphilised. It will be borne in mind, however, that the last two series have purposely not been followed up exhaustively, and that the proportion tainted with syphilis is not improbably greater than appears at present. Again, from the evidence of these series of cases there is no doubt that we may vaccinate from a tainted vaccinifer without conveying syphilis; and, on the other hand, it is possible to convey syphilis either with or without the production of a normal vaccine vesicle. Vaccination from a child evidently syphilitic is known to have been done inadvertently several times without bad result, and probably it has often occurred without being known. These points of clinical evidence make it highly probable that the syphilitic virus is not contained in the vaccine virus, but is derived from, or associated with, some cell-elements of the blood, and probably these need not be visibly red. This is confirmed by experimental evidence, for syphilis has been successfully produced by inoculating the blood of a patient in the secondary stage, and in the case referred to the dates, &c., agree closely with those observed in the author's series. Next, need blood be used in vaccination in order to convey syphilis? The author thinks that probably it is enough if the material used has been mixed with colourless exudation from the blood as occurs when the vaccine vesicle is allowed to drain in order to furnish more lymph. This is confirmed by the fact that the vaccinators in the cases in question asserted that they always scrupulously avoided making the vesicle bleed; in none of the instances is there any history that the lymph was visibly bloody; while it is well known that many men of large experience do allow the vaccine vesicle to weep. According to this supposition, as soon as the first contents of the vesicle are exhausted the risk begins. Third: If the syphilitic virus and the vaccine virus be implanted at one and the same time, what will be the course of events? If the patient is susceptible of vaccination the vesicle goes through its usual phases and heals, and nothing more happens till the end of a month, when the scar indurates and the chancre forms. In some cases, however, the vaccination sore never heals, and in these the scab somewhat obscures the characters of the chancre.

Characters of the vaccination-chancre.—It begins as a little, red, firm, glossy tubercle, which gradually increases in size, and becomes harder. In about a fortnight it usually ulcerates, the sore giving off but very little discharge, and with a hard base and edges. If no mercury is given it may remain open several months; in one case it probably became almost phagedænic. Sometimes there is from the first a good deal of inflammatory effusion at the base of the sore, and much purulent secretion and scab on its surface; its specific characters may be thus quite hidden. These cases are generally in children.

Treatment of the Vaccination Chancre.—Mr. Hutchinson feels no doubt that should a vaccination scar take on the induration characteristic of a chancre, and should the other facts of the case corroborate the suspicion, it is the surgeon's duty without delay to commence the administration of mercury. The influence of mercury in retarding and greatly diminishing the severity of the primary and secondary symptoms was most marked in all those cases which came under care at an early period (sixth week), as in the first series. Indeed, in this series the eruption was so retarded as to induce scepticism in not a few minds as to the correctness of the diagnosis; several of them, however, from five to seven months after vaccination had undoubted, though mild, secondary symptoms. In the second and remaining series of cases, however, the disease was not discovered until much later, and most of them suffered very severely from secondary symptoms, the last two cases (third and fourth series) particularly so. As regards tertiary symptoms, it is yet too early to say anything concerning the primary and secondary symptoms. Mr. Hutchinson says:—"I cannot speak too strongly as to the vast apparent advantage of the mercurial plan. The lesson of the cases is very clearly opposed to the too prevalent modern doctrine that it is well to wait for secondary symptoms before commencing specific treatment, and would appear to indicate that the latter should be adopted as soon as ever the condition of the chancre permits of an accurate diagnosis."

As regards *prevention*, Mr. Hutchinson thinks it of the first importance to diffuse the knowledge that vaccination-syphilis is possible widely amongst the profession; until all Medical men believe in it, and fear it, we shall still be very unsafe. It is important next to avoid vaccinating from children whose parents are not known to the vaccinator; and further, to decline, for the most part, using all first-born children, waiting until by the development of one healthy child a guarantee of freedom from taint on the part of the parents has been given. Lastly, the avoidance of blood-stained lymph and of recent exudation from the walls of the vesicle is a sufficiently obvious precaution, and needs no further mention.

Dr. George Harley said the question was difficult to solve whether there was any danger of syphilis through vaccination. The point of greatest importance was how long does the poison remain in the system? Mr. Hutchinson had referred to cases where blood had been inoculated; he remembered seeing in Munich about twelve years ago a woman, aged seventy, who had between the shoulders a large chancre, produced by blood taken from a patient on whom the secondary symptoms were just disappearing, and injected under the skin. So that syphilis can be conveyed by the blood. Then what interval should be allowed to intervene before it was considered safe to vaccinate from a child who had secondary symptoms? He mentioned a case to prove that ninety-three days may pass before symptoms appear. He agreed with Mr. Hutchinson in not thinking that syphilis could be conveyed by pure lymph, but thought it would if blood or pus, or mucous corpuscles from the walls of a vesicle, were inoculated. Security could only be obtained by using the first drops taken from the vesicle; in this way there would be no danger to the Profession or to the public.

Mr. de Merio said there was no doubt as to the conveyance of syphilis by vaccination, but vaccination must have been carefully performed in this country, as mishaps have been known in Italy and Germany, and not here except in Mr. Smith's case. He thought the period for vaccination ought to be extended to the sixth month, and then there would be time for the symptoms to appear; for an infected child may appear quite healthy at the third month. Vaccination from the heifer should also be employed at times. The ex-royal family of Naples were thus vaccinated, and why should not others have the same advantage?

Mr. Henry Lee said that the cases appeared complete, but it was not shown that the patients had not themselves had syphilis; for if once a person had had syphilis, vaccination relit it up. The worst case of secondary syphilis he had seen was in a gentleman after vaccination; symptoms had been set up lasting for years. That some take it and not others he thought might be explained by the fact that syphilis was not a persistent disease; it had its time of development; it subsided and recurred. If lymph taken from a person likely to have an outburst were used, syphilis would be likely to follow.

Mr. Hulke enquired if the second of Mr. Hutchinson's cases had been under his care at Moorfields, but was answered in the negative. He enquired because he had met with a case there. So that this makes another case.

Dr. Ballard said that some vaccinators, if blood were drawn, carefully wiped it away and used the lymph that afterwards escaped; but this he thought nearly as bad as using the blood.

Mr. Savory said that every unprejudiced mind must now admit that syphilis could be transmitted by vaccination. The fact is less surprising, as fluids transmit syphilis; for if a child is born syphilitic we have to go to the semen, something derived from the blood. In vaccination-syphilis, a child with disease propagates it to another. Constitutional syphilis may be transmitted from a man to a woman without her conceiving by him, but usually it occurred through the child becoming syphilitic; they might cohabit for a long time without syphilis, but if she conceived then she acquired syphilis, and these facts were equally strong for the transmission of syphilis by vaccination.

Mr. Brudenell Carter remarked that he had often seen vaccine lymph in tubes with flocculent matter which might easily carry the syphilitic virus.

Mr. Morrant Baker said that if six persons were to be vaccinated, one—say the third—being syphilitic, that third probably conveyed the disease to the others if the same lancet were used; for blood was always drawn in vaccination.

Mr. George Cooper said that having been a public vaccinator for twenty-seven years, he had vaccinated many thousands, but never seen a case of syphilis after vaccination. He believed that if the vesicle were not wounded, and only pure lymph used, syphilis could not occur.

Mr. Hutchinson, in the course of his reply, said that as to how long we should wait to avoid danger from an infected person, all would agree that if a person has once had syphilis it would always be dangerous to vaccinate from him. With regard to his cases and their value, in the first the man had a chancre and nothing else formed. As to the vaccinifer in the second case, that child and an older one suffered from ulceration of the anus when teething; the surgeon who attended the child said he had no doubt it was a condylomatous growth; so the vaccinifer was syphilitic. Then the duration of the syphilis in the family was interesting. This child was born six years after marriage, and three years after the second. These were somewhat alarming facts as to the latency of the syphilitic virus. When the surgeon vaccinated the child he could not have supposed it was syphilitic; there were no symptoms then, and, if questioned, the mother could have shown her eldest child healthy. This mother had a baby at the breast, and she had promised to bring it to him that he might see if it showed signs of congenital syphilis. The laws of latent syphilis needed to be investigated. Some say that children never have it long latent—never show it after the fourth month. Mr. de Mério's proposition was good as to the age of a child when vaccinated, but he believed the blood could convey the taint, and yet no symptom be found in the vaccinifer, and the child might pass through infancy and only show it at puberty, as by iritis, &c. There was not any weak point in the second case. In the first case vaccination-syphilis was not so clearly proved. Two children had died; but he could get no symptoms of syphilis, and had only the physiognomy of the vaccinifer to prove it at present. He had not spoken of vaccination from the heifer, as he did not think it came into his paper. He did not think compulsory vaccination could be maintained unless we allowed children to be vaccinated from other sources. As to the risk run in his second case, the lady wanted to be vaccinated from a heifer. The surgeon at last said this child was healthy, and used it, and syphilis followed; so there was difficulty in saying the child was quite free. There were no facts to prove that the persons were the subjects of syphilis before vaccination. Vaccination might affect a previously diseased constitution, but could never bring out in a person previously healthy symptoms of primary and secondary syphilis. If the gentleman in whose practice the second series of cases occurred had been asked, he would probably have said the same as Mr. Cooper.

◆

THE SURGICAL SOCIETY OF IRELAND.

The Society met on the evening of Friday, 17th January.

The President of the College of Surgeons, Dr. Kirkpatrick, in the Chair.

Dr. Henry Kennedy read a paper

ON THE USES OF HEMLOCK, IN RELATION WITH THE SCEPTICISM WHICH NOW PREVAILS ON THE VALUE OF DRUGS.

Which will be found *in extenso* at p. 109.

The President said he could endorse Dr. Kennedy's statement that hemlock had been generally used in very small doses and in combination with other drugs.

Dr. E. Hamilton could bear testimony to the value of hemlock in certain surgical cases. He had used it with benefit in some forms of ulceration difficult to manage, arising either from syphilis or struma, and the abuse of mercury combined. He had in his recollection several cases in which this species of ulceration resisted every kind of treatment, until he used the succus conii in large doses, such doses as to produce a certain amount of giddiness or a narcotic effect on the brain. Unquestionably, when hemlock was pushed in this way the improvement was very marked. He had, in his recollection, a patient with whom every kind of treatment was tried, but nothing gave him benefit until hemlock was adopted. He tried it on that occasion at the suggestion of his colleague, Mr. Colles, who frequently used it, and it was rather a favourite remedy with them in Steevens's hospital. He had used it very often in private as well as in hospital practice, and he had found it a very useful medicine. It was not easy to explain the way in which it produced the benefit, but the fact stands that in those cases of ulceration referred to its effect was beneficial. In certain cases of stricture of the rectum it was a valuable remedy. Given in combination with taraxacum in two-drachm doses, producing soft evacuations and allaying the pain of the disease.

Dr. Stapleton could bear out what had been said of hemlock in cases of ulceration of the legs, but they should recollect that they had another drug, opium, which acted wonderfully well in those cases when given in large doses. Hemlock dilated the pupils more or less, while opium contracted them. There was nothing new in giving large doses of opium or of hemlock in cases of persistent ulceration, particularly of the legs. He agreed with Dr. Kennedy that perhaps, as a general rule, sufficient doses were not given; but he should like to know what Dr. Kennedy considered to be the specification of hemlock, what part of the nervous system it acted upon, how it acted, and how they were to know that they had arrived at a sufficient dose, and when they were to stop? He believed the late Dr. Graves used hemlock in chest affections and in whooping-cough, and it had been used in glandular swellings of the mamma, and once had a great reputation in scrofulous diseases. But, again, he asked, how were they to know when they came to a dose that was poisonous, and what part of the system did it affect? He would also ask Dr. Kennedy if he had ever used the alkaloid of hemlock, which could always be relied on to produce its effect, whereas the succus or the extract might be perfectly useless and inert?

Dr. Robert Montgomery could fully corroborate Dr. Kennedy's statement as to the child he had attended along with him. The child had been for some time previously suffering from a large swelling, which did not yield to treatment, and the case was going from bad to worse. When Dr. Kennedy saw the patient he advised hemlock, and under that treatment the child became well. It even relished the medicine; its appetite improved very satisfactorily, and there was no unpleasant symptom whatever.

Dr. Fleming endorsed the view of Dr. Hamilton as to the great value of the succus in combination with taraxacum. He had seen it of great service in what were called lupoid ulcers, and in chronic affections of the testes the use of that preparation had been productive of the most beneficial results. He had seen swellings of this gland as large as a goose-egg, and all the tumefaction and hardness ceased under the use of this remedy joined with bark and in other cases with iron.

Dr. W. P. White said if he remembered aright, the views put forward by the older surgeons a hundred years ago bore out the opinion expressed that evening as to the value of hemlock in those diseases which affected the glandular system. During the last sixteen or seventeen years he had been endeavouring to carry out some observations on the use of hemlock. He began in 1856, being placed in a country district where it was easily obtained, and he adopted the free use of it in a large number of cases both externally and internally. The cases in which he found it of most value were those of young persons suffering under glandular affections, in which cases he used it internally, and in many instances when the gland had run into a sore he used fresh hemlock externally. He had also found hemlock of great value in affections of the prostate gland—not the enlargement met with in old age—but the subacute form of prostate enlargement where the patient suffered from retention of urine depending on some inflammatory action, not of an extreme character and where there was a necessity for catheterism. In such cases he had administered hemlock, giving five-grain doses every three or four hours according to the nature of the case. In cases of phthisis the succus conii was a valuable sedative, producing rest at night, allaying the racking cough, and being free from the objections to which morphia was liable.

Dr. Kennedy expressed his gratification at the discussion which his paper had elicited. He was familiar with the treatment of the class of ulcers referred to, by means of hemlock, and knew that it had been found beneficial in such cases. With respect to the specific effects of the drug he must leave Mr. Stapleton to the writers on the subject. Those effects were very well known, but he must say that as a general rule it was the extract which must be used, as it would be found difficult and dangerous to employ the active principle of the drug in general practice. Mr. Stapleton had alluded to the fact of opium being useful in ulcers, but he contended that hemlock was more useful. Opium disagreed so much with many people that they had repeatedly said they would rather bear the disease they had than be cured with opium. Hemlock was a more genial medicine; it not only did not disagree with the patient but it improved his appetite. With regard to the doses they might begin with an adult with from six to eight grains of the extract three times a day; and with the succus they might begin with a drachm. The latter had one objection as a medicine for children, namely, the quantity of spirit in it.

NEURITIS OPTICI.

Mr. R. Swanzy said a girl, æt. 19, presented herself at the National Eye and Ear Infirmary in November last, complaining of the vision of both eyes. She was extremely chlorotic, so much so that a medical man of great experience in this city said he had never seen such a case. Menstruation commenced in her seventeenth year, and had been performed regularly since then, but the discharge had always been scanty and attended with pain. She first complained of her sight two or three years ago, but it seemed from her description that her trouble at that time depended chiefly upon asthenopia due to hypermetropia. About two years ago, however, she perceived a rapid diminution in her power of vision, and from that time must be dated the complication to which he wished to direct attention. When she came first to the infirmary her vision was only one-half of what it normally should have been; and on examination with the ophthalmoscope Dr. Fitzgerald found the existence of a neuro-retinitis in each eye which he had represented very faithfully in the drawing now exhibited to the Society. The appearance which the fundus oculi presented when she first came under observation was more marked than in the drawing, as that could not be taken until she had been some time under observation. At every menstrual period the vision became much worse. When the discharge was more profuse and more normal the vision did not suffer so much as when the catamenia were very scanty. The inflammation extended somewhat into the retina, and the retinal veins and arteries were rather pale, as was also the optic disc when it was not covered with exudation. He did not think there was much doubt but that the neuritis in this case was produced by the uterine disturbance. This was the first case he had seen in Ireland, and it was remarkable how few such had been put upon record, although the leading text-books almost unanimously mention uterine disturbance of this kind as an occasional cause of optic neuritis. It was difficult to find a satisfactory explanation for the causation which existed in such cases between disturbance of the uterus and inflammation of the optic nerve. At the time the eye affection came on, the patient suffered from violent headache and vomiting. That would suggest the idea of the presence of a slight inflammatory action in the meninges at the base of the brain, which had crept down the optic nerve, and presented itself at the disc. He thought the treatment in such a case should be antiphlogistic at first. He would treat the optic nerve and would not treat the chlorosis or affection of the uterus until after he had got some hold of the affection of the optic nerve. They knew how difficult of treatment such uterine affections were, and how many months it took before they were got under control. If they neglected the optic nerve until they had cured the uterine disease, they might find when they came to treat the former that their patient was blind, for the neuritis would not wait until the uterine disease was cured—it would go on to produce permanent changes in the nerve, and atrophy of the optic nerve resulting in blindness. He would therefore recommend that the treatment in such cases should be in the beginning antiphlogistic, locally by the use of the artificial leech, and the wearing of blue spectacles, and generally by slight mercurial inunctions if the patient could bear them. He had thought the case worthy of the attention of the Society, being of such general practical interest.

Dr. MAPOTHER wished to ask a question as to the causation of blindness in these cases? He would ask was it at all compatible with anæmia of the retina which might occur in these extremely chlorotic patients? They all knew that in children from the retraction of the retinal vessels considerable blindness might occur, this contraction arising from irritation of the intestinal canal from worms.

Dr. CHARLES E. FITZGERALD could confirm the remarks of Dr. Swanzy as to the case, but he differed with him regarding the treatment. He could, however, scarcely consider himself fully competent to give any opinion on it; for this was the first case he ever saw of the kind. Dr. Swanzy having studied under Prof. Von Graefe had had larger opportunities of seeing such cases, but the treatment which he recommended, and which was the treatment pursued by Von Graefe, was a treatment which as far as he (Dr. Fitzgerald) was aware had never been pursued by any othor ophthalmologist. There were on record very few cases of this form of disease. The only one he was aware of that had been fully recorded was one mentioned by Mr. Hulke in his work on optic neuritis, and his treatment was not of the class recommended by Dr. Swanzy. At the time the girl came to the Hospital he (Dr. Fitzgerald) happened to be on duty, and undertook the treatment of the case. He tried hypodermic injection of strychnia, and it had a beneficial effect, but the girl left the Infirmary, went to a situation, and returned some few weeks ago with the chlorosis greatly intensified, having left off the treatment she was under before. She had been taking large doses of sulphate of iron. However, as Mr. Swanzy recommended it, he tried the artificial leech, and yesterday it was applied, but although she bore the incision perfectly, the moment the exhausting glass was applied she fainted. Although that might not be a strong contra-indication of the use of the artificial leech, he would be very cautious of trying it again, at all events, until the patient was stronger. He might mention that the enlargement of the drawing now exhibited to the Society was 19¼ diameters of the normal disc.

Mr. SWANZY in reply said he did not think the anæmia had produced the neuritis. He did not think chlorosis necessary to cause the affection. This affection was not at all common; he had only a distinct remembrance of two cases; he thought he had seen three, but in none of those cases was there chlorosis. There was one disease of the blood which caused remarkable changes within the eye—namely, leucocythœmia—they found in such cases a peculiar form of retinitis, a true exudation of the white blood corpuscles. But he did not think that anæmia had anything to do with producing the peculiar affection in the present case. His own idea was that in consequence of the suppression of the menses or of their scantiness, there was hyperæmia at the base of the brain, and that this went on so far as to turn into a slight inflammation which presented itself in the form of optic neuritis. He could not, however, say this positively. He continued to think his ideas of the treatment to be pursued were correct for the reasons he had stated. As to the hypodermic use of strychnia, which had been introduced by Prof. Nagel, of Tubingen, it was doubtless a most valuable remedy in some cases of amblyopia, but he (Mr. Swanzy) would not commence to treat an inflammatory affection of the optic nerve, or disc, or retina with strychnia. He might at a later stage use strychnia after having treated the case antiphlogistically. They had no cases on record to show that strychnia did good in these affections, and *à priori* he did not think it would. He knew that it had produced a temporary beneficial effect in this instance, but he did not think the effect would be lasting. As to the girl fainting when the artificial leech was applied, he attached no importance to it. Not long ago he had to treat a gentleman from the country, a very strong man, a huntsman, fond of field sports and active exercise. He had an affection of the eye which made it desirable to apply the artificial leech, and the moment it was applied he fell down on the floor in a faint. Such an occurrence is not very uncommon, but must not be regarded as a sign of great debility in the patient which would contra-indicate the proceeding.

CONTRACTED FINGER.

Mr. MORGAN said he wished to bring under the notice o the Society the subject of crispatura tendinum, and the best mode of curing the contraction of the fingers known by that name. He exhibited a number of casts representing various conditions of this contraction. The name given to it by Boyer indicated that it was a contraction of the tendons themselves. In some instances that might be the cause, but in the generality of cases it was not, and there was some obscurity as to what was the exact offending cause in this disease. It was exceedingly intractable. Within the last few days he had removed the finger which he now exhibited. The patient was a man of 35. About two years ago his hand was caught in a plank of wood, which tore open the first joint, and subsequently the finger became greatly contracted. Nothing would satisfy the man but the removal of his finger, as it was greatly in his way in working at his trade, that of a shoemaker. He accordingly removed the finger, and he had since and also before the operation, endeavoured to find out what was the offending point. He had arrived at the conclusion that this was the contraction of the lateral ligaments, and he therefore suggested that the division of those ligaments, a procedure which had never yet been tried, ought to be adopted in these cases. Of course, this would not answer where the palmar fascia was affected. The question then arose, was this contraction of the lateral ligament secondary or primary? Was there first contraction of the tendon and then thickening of the ligament? He was inclined to think there was contraction of the tendon, and in consequence of it this shortening of the lateral ligament.

Mr. STAPLETON thought it was irritation of the nerve which generally caused these contractions.

Dr. W. P. WHITE thought Mr. Morgan's suggestion was admirable for the class of cases to which he referred. He had seen numbers of cases of this kind. For instance, there was the contracted hand, common with coachmen, where the entire of the palmar fascia became contracted. He had also seen cases in old gentlemen which he could only attribute to some nervous influence. Within the last four years he had seen several cases of men in a good position in life, where the hand was contracted, although there never was developed gout in the hand, and where the disease evidently arose from gouty poison affecting the nervous system. He thought Mr. Morgan's suggestion of dividing the lateral ligaments in those cases where the disease was not in the palmar fascia, was deserving of attention.

The PRESIDENT recognised one of the casts on the table as that of the hand of a gentleman whom Dr. Elliot had attended along with him. The contraction was mainly dependent on the palmar fascia, and though Dr. Elliot had devised some very ingenious apparatus, and performed sections of the fascia in the most skilful manner, still the result was not successful; and it confirmed him in the opinion that in cases where the palmar fascia was very decidedly engaged, it was better for the surgeon to remove the finger. The only case in which operation would succeed in restoring the finger to its normal condition, was where the tendon only was at fault, and not the fascia.

The Society then adjourned.

ERGOT IN HEADACHE.

D. R. SILVER, of Sidney, Ohio, states in the *Medical and Surgical Reporter*, that ergot is better for headache, than any other single article of the materia medica. He recommends it to patients who are subject to the malady thus:—℞. Squibb's fl. ext. ergotæ, gtts x—xx for one dose. To be repeated every half hour until relief is obtained, or four or five doses are taken. The primary effect of opium is to produce hyperæmia of the brain. To neutralize this action Dr. Silver employs with it fluid extract of ergot, and says the combination has a happy effect in cases in which opium alone would be contra-indicated by the fluxion of the brain. He does not regard ergot as a specific for headache, but thinks thousands of people are made miserable once a fortnight or once a month, who, by the use of it, may be made, for the time, comfortable. His experience with ergot in the headache of fevers is limited; but he would expect no good result from it, since the pain is then, probably, produced by the abnormal temperature and *quality* of the blood, instead of being occasioned by fullness of the cranial vessels, as once supposed.

REGISTERED FOR TRANSMISSION ABROAD.

THE
MEDICAL PRESS AND CIRCULAR
is published simultaneously in London, Dublin, and Edinburgh, every Wednesday morning. Price 5d. Post free, 5½d.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 5, 1873.

THE IRISH COLLEGE OF SURGEONS AND ITS REPRESENTATIVE.

As we have said in another part of our issue, the Council of the Irish College of Surgeons received at its last meeting the opinion of their law advisers on the question of the legality of their present position with regard to the Representative of the College in the Medical Council. The authority of Mr. Hargrave's tenure of office was challenged by us, as our readers will remember, on two grounds—firstly, because his term of office was extended from one to five years by an unauthorised interlineation in the Council Minute Book, and secondly, because Mr. Hargrave was re-elected three months before his previous term of office had expired, and, therefore, before the office was vacant.

We have the satisfaction of being aware that the opinion of Mr. Frederick Walsh, Q.C., whom the Council consulted, entirely corroborates that which we put forward in our last publication. Mr. Walsh expresses very decidedly his opinion that the resolution in which the interlineation appears was "irregular and informal, and that the course pursued on that occasion was highly objectionable and such as ought not to have been allowed." But, though he is of this opinion, he does not see his way in advising the College to take action in the matter.

He thinks it also within the power of the Council, at a duly convened meeting, and in pursuance of a proper notice for the purpose, to proceed (previous to the expiration of the term for which its representative had been elected) to nominate and choose his successor. He is, therefore, of opinion that the fact of Mr. Hargrave's election being held before the expiration of the term of four years for which he had been elected in 1865, does not invalidate the election.

Mr. Walsh also considers that the election of Mr. Hargrave "could and ought to have been set aside," but does not think it could now be done without the consent of the Council and Mr. Hargrave; and he further expresses his opinion that considering the fact that Mr. Hargrave and most of the gentlemen now on the Council were parties to a transaction quite contrary to their ordinances, and in violation of their rules, and illegal, it would be but becoming on the part of the Council and Mr. Hargrave to proceed at once to a new election.

The Council having received so explicit an opinion from their legal adviser have, we understand, taken the earliest steps to amend their error and remedy the illegality of their previous act. At a special meeting on Friday last the subject was taken into consideration, and a resolution was, we believe, unanimously adopted that Mr. Hargrave be requested to take into consideration the propriety of resigning. It is furthermore reported, though we find a difficulty in crediting the statement, that that gentleman, being then present, gave the Council to understand that he would not comply with their request, but would, without doubt, attend the approaching meeting of the Medical Council in March, as their Representative; and that, thereupon a Notice was given by a member that he would, at the next meeting move that, inasmuch as the Council was advised that Mr. Hargrave's occupancy of office was illegal, and that it would be proper to proceed to a new election, the office be now declared vacant, and that the Council proceed on a stated day to fill the vacancy.

We have reason to hope that Mr. Hargrave will not persist in his most unjustifiable and ill-judged refusal to vacate an office which he no longer fills with the confidence or authority either of the Council or the College, but if he should place himself in so false and untenable a position, we have every confidence that the Council will not hesitate, in compliance with the legal advice which it has received, to undo its former illegal act, and put itself and its Representative in a just position before the Fellows and the Medical Council.

◆

BALMFORTH v. BUCKLEY AND FLETCHER.

IF anything can assuage the sorrow and vexation that fall to the lot of a man unjustly accused of malpractice, it must be the hearty support of his brethren. This support has been expressed in a striking manner towards the defendants in this action, who we learn from the *Manchester Courier*, were last week presented with a testimonial of continued confidence and thorough support, which furnish an index of the feeling of their brethren throughout the country.

It will be remembered that at the South Lancashire Assizes, in August last, actions for damages for alleged negligence by the defendants resulted in a verdict of 40s. and costs against them. A number of sympathising brethren, considering that they had used proper care and diligence, started a subscription, which met with a ready response from 221 Medical men in fifty different towns, including the metropolis, and at a public meeting, Dr. Royle presiding, Mr. Buckley and Dr. Fletcher have been presented with £210, the amount subscribed, after expenses had been deducted.

Dr. Royle, in making the presentation, said they must not look at the result of their efforts as simply a sum of money collected for a special purpose—the great value which the two gentlemen in question would attach to it was the fact that it was the result of the spontaneous good feeling of their professional brethren not only there but in the neighbourhood round about Manchester, in which it was their privilege to live. There was no doubt that the gentlemen who first saw the man after the accident, which occurred in Yorkshire, and Mr. Buckley and Dr. Fletcher afterwards, did all which their skill would allow, they acted to the best of their judgment, and certainly had not the slightest desire or wish to neglect the man, or to neglect anything which to the best of their skill and ability they could prevent. Dr. Royle went on to show that when a man did to the best of his ability and power in a profession which so taxed the energies and wore out the body in services very often to an ungrateful public, it was right for them to protect such men in the discharge of the duties of their profession. There was no profession to which so much individual responsibility attached, and that difficulty was increased by the unfair and unprofessional conduct of men who were employed in it. This, he said, only showed that they ought to stand up for their profession. They were only the servants of the public, and their glorious profession was to be exercised for the public good, and no other. What a monstrous thing, he exclaimed, that the profession would not be true to itself! He held himself ready to defend any professional brother against any outsiders for malpractice, so long as that professional brother had done his best. It was a lowering of their position to take a special case on its merits or demerits, whether their friends had made a blunder or not; there was no judgment on earth but what was fallible—the best, the ablest, and most skilful of men might be deceived by the peculiarities of constitution, or the disposition of the patient, or by the phases which disease put on, which might escape the detection of the most acute, and therefore it was their duty to be charitable in giving an opinion one against another.

Words thus spoken under such circumstances deserve to be repeated on every suitable occasion, and we have therefore drawn upon Dr. Royle's speech in putting the case before our readers. If only Medical men would act in the manner thus inculcated, we should find not only that the respect of the public would increase, but some of the saddest dissensions that now occur in our ranks would completely disappear.

We need not say that Dr. Ogden Fletcher and Mr. Buckley returned heartfelt thanks for the indication of the feeling of their brethren shown by the testimonial, which they naturally regard as of far more value, even to them, than the cheque itself. May they and every subscriber long live in peace, and may the example of this case tend to bind Medical men everywhere more closely to each other!

WOOLWICH WORKHOUSE INQUIRY.

"When ignorance is bliss 'tis folly to be wise" seems to be the motto of the Woolwich Poor-law Guardians, five of whom, it would appear, belong to that profession yclept "Reverend," now rather distinguishing itself in so unpriestly a manner around us. During the proceedings of a recent Poor-law inquiry at Woolwich, a Rev. Tuffield went in at high pressure for exorcising the [illegible] on account of being "very technical," which [illegible] teaching the Guardians the simple A B C [illegible] duties towards the poor under their control. As a simple illustration of the impudent ignorance of Rev. Tuffield in matters in which he meddles, we append the following from a published report of the recent inquiry:—

He, "Tuffield, attended the *post-mortem*, and found (he, Tuffield, did!) that not only was it unnecessary, *but it was carried to an unnecessary extent: the cause of death was consumption, yet the doctor persisted in opening the head*." The veriest tyro knows that a coroner's warrant orders the special examination of the head of the subject on whom a *post-mortem* may have been considered necessary (and all viscera likewise), and *no* doctor would be justified in excluding the head *(under any consideration)* from examination. Indeed, as a rule, coroners inquire of the Medical evidence if the head, heart, lungs, kidneys, &c., have been examined. Rev. Tuffield has much to learn, we apprehend, and we would advise him to resign his seat on the form of the Woolwich Poor-law Board, humiliate himself for once, show an example to his flock, and take, with a Christian's fortitude, to a lowly seat on a lowly form, in one of those lowly habitations wherein the School Board's masters instruct.

In the case under notice the facts are as follows:—A patient died at Woolwich; foul play was suspected, bruises being on the body of the patient. The coroner was communicated with; an inquest was ordered by him; and, *because the doctor obeyed the coroner's warrant*, Rev. Tuffield not only intrudes his priestly presence, but subsequently raises his heels to kick at a Medical gentleman for showing his "technical" training by simply doing his duty. We call on the Poor-law Board to protect their officer, and we shall anxiously watch the proceedings they may take in order to teach the Woolwich Poor-law Guardians how to conduct themselves.

◆

Notes on Current Topics.

The Right of Election of the Medical Council.

The Council of the Irish College of Surgeons received at its last meeting the opinion of its law adviser, Frederick Walsh, Esq., Q.C., respecting the legality of the election of Mr. Hargrave as Representative of the College on the Medical Council, to which we have referred elsewhere. The Council had, at the same time, asked the opinion of their law advisers as to the general question, whether the election of a representative lay in their hands, or in the hands of the Fellows at large. Taking this latter question first, Mr. Walsh advises the Council that in his opinion the Council represents the corporation for the purpose of electing a representative. By the Medical Act (1850), sec. 4, it is provided that the General Council shall consist of, among others, "one chosen from time to time by the Royal College of Surgeons in Ireland."

By the 7th sec. of the Supplemental Charter, it is provided "that the Council are to exercise the powers and privileges, and perform the duties and functions of the said body politic and corporate as the governing or executive Council of the College, and *in all respects to act for and on behalf of the said College, as lawfully representing the same.*"

Mr. Walsh states, therefore, that he entertains no doubt whatsoever that, under these provisions, it is the Council which is to choose and nominate the person to represent their body on the General Council.

It might be argued on the other side that the proper construction of the clause of the Charter, quoted by Mr. Walsh is, that the Council, being the "governing and executive" body, was empowered to act *as such*, "on behalf of the said College," but that their authority under the clause does not extend beyond the limits of "governing and execution" or administration, and that the election of a representative on the Medical Council does not come within such function. This view is strengthened by the wording of the first clause of the Charter, which says that 'the Fellows of the said College shall exercise and enjoy all and singular the gifts, grants, liberties, privileges, and immunities, possessions real and personal whatsoever, *by any Act or Acts of Parliament*, or by any letters patent, granted and confirmed unto and lawfully acquired by the said body politic and corporate."

Although we put forward this view for the sake of argument, we do not suggest that the question need be raised in any other form. The Fellows of the College, if we understand their feeling on the subject, are not disposed to take the power of election from the hands of the Council, and only desire to see the interests of the College guarded by the selection of a competent spokesman on its behalf. It will, certainly, be the duty of the Council at the coming election of a Representative to ensure that the delegate selected shall be entirely under their control, and that the Council shall not again find itself in such a dilemma as it is now placed in. In no case should the tenure of office be longer than one year, for no difficulty has ever arisen in the re-election of a representative who enjoys the confidence of the Council, and, as the tenure of office is not terminable by the Council, it should not be an extended one.

Pauper Extras.

We quoted, last week, from a local paper into our Supplement which is devoted to Irish Poor-law Medical affairs the report of recent proceedings of the Waterford Board of Guardians, to which we think it right to refer, inasmuch as the authority of the relieving and Medical officers to order such nourishment and stimulants as they may think necessary, is seriously involved in the considerations which arise from the matter. It appears from this report that Dr. Cane, the local dispensary surgeon, had ordered creature comforts for an outdoor pauper to the extent of £1 6s. per week. The Board of Guardians addressed to that gentleman and to the relieving officer a request to be informed of the grounds for so large a weekly grant.

Dr. Cane replied by informing them that "the relieving officer was the only person who could reply to the question, and as it was foreign to his (Dr. Cane's) business to meddle in such matters, he trusted the Board would not refuse to remunerate him for writing the said reply."

The relieving officer also stated that he regretted "he could not comply with the recommendation of the Guardians to reduce the amount of relief or remove the patient to hospital."

As a rider to this statement, a further requisition from Dr. Cane was read, in which he recommended the following additions to the weekly grant of £1 6s.:—"To increase the 14 glasses of brandy weekly to 20; to give a quart of milk daily, and to order also a chicken, 4 pounds of beef for soup, and 3 pounds for frying on a gridiron."

We further observe that at the following meeting of the Guardians, a *locum tenens* having been meanwhile appointed in Dr. Cane's place, the woman was certified as fit to be removed to hospital, and was accordingly removed.

It is just possible to conceive that a case might exist in which so monstrous an amount of nutriment and stimulants might be necessary to preserve life, but if so it is obvious that the patient could not be considered fit for removal to hospital. We are obliged, therefore, to regard such a grant as a most unjustifiable abuse of the authority enjoyed by the relieving and Medical officers, and, in the interests of Poor-law Medical officers, a subject for regret and deprecation. Dr. Cane and his relieving officer, so far from vindicating a principle or a privilege, have acted so as to bring into contempt the authority given to them, and have placed in the hands of skin-flint guardians a weapon which may be used against the dispensary doctor whenever he sees fit to order extras to the paupers under his care. We think the Local Government Board might advantageously express their opinion on the matter.

The Dispute between the Professor of Anatomy and the Board of Trinity College.

An investigation was held in the University of Dublin on Monday week, before the representatives of Lord Cairns and the Archbishop of Dublin, the visitors of the University, into certain disputes between Dr. McDowel, the Professor of Anatomy and Chirurgery in the School of Physic, and the Board of Trinity College. The limited space at our disposal does not enable us to enter into the subject more fully than to state the facts.

The Professor of Anatomy and Chirurgery is by the School of Physic Act (40 Geo. III., cap. 84, sec. 11) *ipso facto* Surgeon to Sir Patrick Dun's Hospital.; he is elected to the Professorship for seven years, and re-elected if thought fit; and if he wilfully neglect to perform the duties of the professorship he may be admonished and deprived of his professorship. In 1846 Dr. McDowel was chosen Surgeon to the Richmond Hospital, and in 1858 was elected Professor of Anatomy as before stated. In 1865 he was re-elected, and still continued to hold the surgeoncy of the Richmond Hospital, in addition to Sir Patrick Dun's. In 1869 Dr. McDowel was removed from the surgeoncy of Sir Patrick Dun's on a charge of "irregular and insufficient attendance," but without any open inquiry, which was repeatedly demanded by Dr. McDowel. This transaction created at the time much excitement amongst the Profession in Dublin, and was the subject of a special meeting of the Fellows of the Royal College of Surgeons, as will be found recorded in the pages of the Medical Press of that date. In October, 1872, the third septennial period of Dr. McDowel's professorship would expire, and advertisements were issued by the Board of Trinity College, in which it was set out that "no University Professor can hold an appointment as Medical officer to any clinical hospital other than that of Sir Patrick Dun." This latter statement was based on a resolution of the Board to that effect passed in 1868, to which resolution the following words were appended:—"N.B.—This rule not to affect existing interests." In October, 1872, Dr. McDowel was re-elected, and certain alterations in the arrangements and emoluments of the professorship were then made, Dr. McAlister being appointed, at that time, Professor of Comparative Anatomy, and a part of the fees which had hitherto been Dr. McDowel's being appropriated for his payment. At the time Dr. McDowel protested against these arrangements, but he was nevertheless re-elected to the professorship. The Board now calls upon him to resign the Richmond Hospital and enter on his duties at Sir Patrick Dun's, and refuses to allow him to take the necessary declaration as a Professor until he does so. Dr. McDowel avers that he "never formed, conveyed, or expressed any intention of resigning" the Richmond, and that he sought re-election under the impression that his "existing interests would remain unaffected as before." He expresses himself as willing to do duty at Sir Patrick Dun's, but protests against being required to do so until the resolution of dismissal be rescinded.

The visitors have, as far as we can gather, to decide—1. Whether Dr. McDowel was elected, subject to his resigning the Richmond; 2. Whether the Board has power to deal with the Professor's fees as they have done.

Chloral Hydrate in Traumatic Tetanus.

Dr. CORYLLOS, of Patras, (Greece), reports in the *Allgem. Wien. Med. Zeit.*, a case of traumatic tetanus, treated successfully with large doses of chloral hydrate. A woman, æt. 70, hurt her right foot with an iron nail on August 27th last. On September 12th, painful tetanic cramps occurred in the right lower extremity, recurring on the least touch, also fleeting spasms of the MM. masseter., and difficulty of swallowing. On the 13th, Dr. Coryllos saw her. He found a small hole in the sole of right foot corresponding to the wound; no suppuration; the right M. gastrocnem. contracted; the other muscles of the limb trembled on the slightest touch; very severe pain along the N. crural. dext.; the mouth could not be opened widely; difficulty of speech; deglutition sometimes good, sometimes the fluids were ejected by the nose; solids could not be swallowed at all; the muscles of the neck contracted, and hence the head could not be bent forwards; patient could sit, but only for a short time; no fever; tongue clean. She was ordered 1 tablespoonful every 2 hours, of a mixture of 1 drachm of chloral hydrat. in 2 oz. of fluid; and ungt. hydrarg., with extr. belladon., to be applied to the painful parts. Two days later, she was ordered 2 drachms of chloral in the day, and 1 gr. of morph. acet., in 8 doses. The pain and cramps immediately began to yield. In 14 days she could go about with crutches. On October 15th, she walked alone. In 14 days, this old woman had taked 18 drachms of chloral, and 4 grs. of morph. acet., and used 6 oz. of ungt. hydrarg., with 6 drachms extr. belladon. There occurred no redness of conjunctiva, lividity of lips, diminution of frequency of respirations, or other symptoms of poisoning by chloral. It seems clear that the patient recovered, but it is not so evident, that the result was due to the chloral hydrate alone.

The Alleged Death from Nitrous Oxide.

EVERY Medical man must feel regret that so little reliable information has been obtained in respect to the fatal case briefly recorded in our last. When we inserted the news without further comment, we assuredly expected that the inquest would furnish us with further data on which to form an opinion, and we cannot but feel that, in the interests of truth, the coroner ought to have ordered a *post-mortem* examination. We know the objections often entertained by friends, but this was just one of the occasions on which it could be urged that information of the utmost value might be obtained by an autopsy. The point raised in the letter that appears in our correspondence deserves attention, and will probably lead to other communications. The question is also closely allied to the controversy about ether and chloroform, respecting which Dr. Hime, of Sheffield, to day takes up the gauntlet that has been thrown down by the etherists.

London International Exhibition, 1873.

ANOTHER meeting of the surgical instrument manufacturers has been held, and they have unanimously resolved that the revised conditions proposed by Her Majesty's Commissioners should be accepted, and that the majority of instrument makers would exhibit.

Vaccino-Syphilis.

THE account of the late meeting of the Royal Medical and Chirurgical Society to be found in another part of the present issue, is of such paramount importance that we trust it will be carefully perused by every one of our readers. Mr. Hutchinson's paper made a great impression on those present, and the general tone of the debate contrasts very forcibly with that which followed his former communication. We may have more to say on the subject ourselves, but we refrain from distracting the reader's attention from the debate, which we doubt not will be studied with the greatest care. It will be remembered that on the eve of this discussion we published the history of a case of vaccino-syphilis that was observed in the Belfast General Hospital. We invite other observations on this important subject.

The March of Cholera.

ON the 18th ult., a case of sudden death from cholera occurred in Vienna. This is the second death from this cause which has occurred. The prospects of the International Exhibition to be opened in Vienna this spring, must be rather clouded by this incubus of a visitation of cholera.

Prof. Bruoke.

IT is with great regret that we announce the serious illness from scarlatina of Dr. Brücke, professor of physiology in Vienna. He is under the care of Dr. Billroth, from whose care all that skill can accomplish may be expected.

Dr. von Pettenkofer.

PROPHETS sometimes do enjoy the honour rightly due to them at home. Dr. v. Pettenkofer, the celebrated Professor of Hygiene in Munich, has been invited to occupy the corresponding chair in Vienna. However, such a strong desire was manifested not only by the municipal authorities, but by the Government to retain so distinguished a philosopher in Bavaria, that he has preferred to accept the advantages offered to him at Munich, to the perhaps greater *éclat* of a Professorship in Vienna.

The German Universities.

THE number of students in each of the German Universities this winter, 1872-73, is as follows:—

Leipzig.—Matriculated, 2,650; non-matriculated, 122. Of these, 894 are natives, 1,756 foreigners. They are distributed as follows :—law students, 863 ; divinity students, 421 ; Medical students, 394 ; philological students, 339.

Berlin.—1,981 matriculated students ; non-matriculated, 1,796. There is a falling off of 72 in the matriculation since summer, 1872.

Munich.—1,219 matriculated students (22 less than in summer, 1872. Of these, 330 are law students ; 74 divinity students ; 355 Medical students ; 383 philological students ; 54 pharmaceutical students.

Breslau.—1,005 matriculated students (an increase of 65 over last summer) ; 36 pharmaceutical students.

Wurzburg.—803 matriculated students.

Bonn.—752 matriculated students ; 44 non-matriculated ; 81 pharmaceutical students ; and 19 voluntary attendants.

Heidelberg.—633 matriculated students, and 74 pharmaceutical students (212 less than in summer, 1872).

Erlangen.—371 matriculated students (12 more than in summer 1872).

Freiberg.—275 matriculated students.

Kiel.—149 matriculated students ; 41 non-matriculated.

Death of Mr. Baker Brown, F.R.C.S.

Just as we are going to press, tidings reach us of the death of this gentleman, who but a few years since was considered one of the most skilful operating surgeons of the age. His practice, chiefly amongst the upper classes, was very extensive, but alas ! the tide of professional popularity suddenly turned ; he fell foul of a certain faction of the Profession on account of his performance of an operation which is very common on the Continent, but which was deemed improper in this country ; abuse *ad libitum* was heaped upon him, until he was finally blackballed from the Obstetrical Society. Poor fellow ! his high spirit and sensitive mind never recovered from this treatment, which we alone, of all the Medical journals, stigmatised as unnecessarily harsh and unjust ; his practice went from him, one illness succeeded another, until he was attacked with cerebral paralysis, which ended on Monday in death from congestion, caused by the sudden accession of cold weather acting upon a brain already seriously disorganised. True, the Profession endeavoured to repair the injury some of its members had done him by subscribing to a fund for his pecuniary relief—a statement of which appeared last month in this journal from the pen of Dr. Forbes Winslow ;—but the time of reparation had passed, and the man who once held so prominent a position, died penniless ! Tis a very sad reflection, but the truth must be told, and we are sorry that the unpleasant task should devolve upon us of telling it. We are informed that it was his express wish that anything connected with him should first be communicated to us on account of our consistent support in the the face of every conceivable opposition, we propose therefore to give a full obituary of the deceased in our next.

◆

Correspondence.

A WORD FOR CHLOROFORM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The vigour of the assault on chloroform seems to have deprived of power to reply those who, from many years' experience of its use, might be able to throw much light n the subject. As it is highly desirable that as much evidence as possible should be collected, *pro et contra*, before rushing to the conclusion that ether should be universally adopted as an anæsthetic, I beg leave to contribute my personal experience as to chloroform. The ethereals argue thus,—We have statistics of a certain proportion of deaths from the use of chloroform : if we knew the whole truth we would have a much larger death rate to show. On the contrary, I believe the worst is known, and perhaps an unnecessary timidity is felt in using chloroform on that account. There are many private practitioners who use it largely, and without accident, but unfortunately they are backward in giving their evidence. Had many accidents occurred in private practice the use of chloroform would have received such a blow that it could not have survived so long. It is in private practice that such an occurrence would make the most serious impression, and raise up an insurmountable obstacle to the use of chloroform. It is, however, becoming more popular, especially in obstetric practice. I have never seen a single serious accident from its employment, either in hospital or private practice, though I must have seen many hundred cases of its administration both on the Continent, in Dublin, and here. In my private practice I have completely narcotised 203 cases in the past four and half years, chiefly in obstetric practice ; in addition to this, I have given it in small quantities in many other cases. I have had no skilled assistance whatever, except in perhaps a dozen cases, but have alone administered the chloroform, and attended to the other necessary obstetric or surgical duties. I have never had anything resembling an accident. I believe there are many practitioners who could give evidence equally favourable to chloroform. As to the sickness which is often found *to follow* its use, I think there is very little evidence to show that it is a result and not merely a coincidence. I have never seen it occur, except in cases of severe operation. I have had obstetric cases completely under chloroform for over an hour, and semi-narcotised for as much as five hours, without any sickness, where there was no serious surgical manipulation necessary. To one gentleman I administered six ounces in two days for very severe tic, without any symptom of sickness. My former master, Prof. Nussbaum, of Munich, has kept a patient narcotised for 72 hours, using ten ounces of chloroform, and out of 15,000 persons he has chloroformed, never had one mishap. The record of etherised cases contains its death roll, though small ; and a pretty large percentage of sickness after administration : *e. g.*, the "Report on the Employment of Ether at Guy's Hospital," in the *British Medical Journal*, Jan. 18th, 1872. In every one of these cases there was sickness ; in most lividity ; and Mr. Carey, who reports them, states that they are "typical of all that have had ether," from Nov. 6th up to the date of writing. I think this point regarding the causation of the sickness is well deserving of attention. If every practitioner would state his experience of chloroform there would soon be abundant evidence, and I believe mostly in favour of it. The worst result I have seen from its use has been temporary difficulty of breathing in a few cases. I believe this has always arisen from giving an excessive dose, especially at the commencement. The administration should be very gradual, I believe, to be successful. For the last two years I have used the bottle devised by myself, and recently described and figured in your columns, and a hollow cone of leather cut to fit over the nose, and having the top cut out, and a piece of sponge stitched in, which though an imperfect apparatus, I find an improvement on all others.

Apologising for the length of this letter,

I remain obediently yours,

Thos. Whiteside Hime, M.B.

COMPILATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Plato, although in favour of treating acute diseases and accidents, stating that invalids are unfit for war, business, or study, considered a weakly life protracted by treatment, little different from long death. Bacon, reminding us that the great Physician of the Soul went about doing good, restoring the leper, the halt, the maimed, the blind, and the paralysed, argues that the duty of the strong lies in the alleviation of suffering. Kingsley, in a curious sermon on behalf of the deaf and dumb, told us that for one worm to speculate why another should be imperfect is a presumptuous sin ; for at any moment the cup of happiness, the enjoyment of life, may be snatched away from the lips of the healthy questioner. A volume might be written on the blind poets, philosophers, and musicians, on the loss of one sense stimulating the acuteness of those remaining, on the clever authors who, in pain and suffering, have in fancy travelled from the sick room to scenes of pleasure—for instance, Hood, propped up in bed coughing and blood-spitting whilst writing humorous poems on the taint of scrofula, influencing the genius of Johnson and Swift—and on the clever children whose parents, brothers, and sisters had succumbed to phthisis. It would be very easy to prove that beauty, talent, and wisdom are but phases of disease. Also there must be something wrong in the constitutions of the muscularly, powerful, the brawny Herculeans, so often intensely idle, stupid, or empty-headed. The more this question is considered the smaller the number of those appears who enjoy *mens sana in corpore sano ;* too, a powerful basis supplied for the argument that disease stimulates enterprise, research, and discovery, and that the strong, instead of originating, only carry out plans concocted by the weakly. The fable of the lion and the mouse becomes a reality. Plato was decidedly wrong. In the "Lives of the Engineers," by Smiles, you will read of John Metcalf, who, through variola, became blind at the age of six. Growing up a strong lad, able to climb trees bird nesting, to ride, and to swim, he saved a drowning man. Clever at bowls, wrestling, and boxing, also a good fiddler, at Christmas he played the "waits," and at dancing parties blind Jack was indispensable. No wonder he married the belle of the village when his dash and accomplishments are considered. During the Rebellion of 1745, becoming a volunteer enlisting 240 men, Jack played a march at the head of the company, dressed in blue and buff, and in a gold-laced hat. How he made 180 miles of good roads, for which he received £65,000 ; how happy he was in domestic life, how peacefully he went to sleep at the age of 93, will interest every reader not excepting the admirers of Plato. Race unfortunately *does* degenerate, the population more weakly, the lunatic asylums crowded, but there is a safety valve in epidemics. Annually, scarlet, typhus, typhoid, in fact fevers generally, restore the balance as regards over-population. Either at Birmingham or Manchester there was a society for advocating the destruction of chronic invalids, mothers-in-law, and people useless or obnoxious to a community, but nothing has been heard lately regarding the progress of such principles. In the *Spectator* it is laid down as a maxim when a nation abounds in physicians it grows thin of people, and those practitioners who have no patients amuse themselves with the stifling of cats in an air pump, cutting up dogs alive, or impaling insects upon the point of a needle for microscopical observation. All this nonsense is counterbalanced by the following observation :—"When I consider how each of these Professions are crowded with multitudes seeking their livelihood in them, and how many men of merit there are in each of them who may be rather said to be of the Science than the Profession, I very much wonder at the humour of parents who will not place their sons in a way of life where an honest industry cannot but thrive, than in stations where the greatest probity, learning, and good sense may miscarry. A sober, frugal person of slender parts and slow apprehension may thrive in trade yet starve in physic." One more quotation rather tickles one's fancy, namely—"Editors and compilers are not reckoned the first literary characters. Their works contain a great deal like chests in warehouses, but the goods are not their own," wrote the brilliant yet gloomy maniac,

HAZLITT.

THE PROPOSED NEW CHARITY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I was much pleased to see the letter in your last number signed A. W. It is quite time some one spoke out on this point, and I hope the ice having been broken, a decided move in the right direction will be made. Perhaps the hint to our legal brethren will do this. When I see men desirous of becoming members of the Medical staff of a hospital or dispensary, and even spending in some cases large sums of money to gain the position, so that they may sign themselves and put after their name in the Directory "Physician (or Surgeon) to the —— Hospital," I think the system calls for a decided reform. I could mention gentlemen who have held gratuitous appointments for seven, ten, and even twenty years without receiving any other benefit from it than the honour (!) and the privilege of paying their railway or omnibus fares to and from the institution, or, if their means permit, of keeping a carriage for that purpose. I would venture to add that had the same amount of time and labour been spent on their private practice, they would have been amply repaid, in most cases with interest. However, if the Medical profession *will* continue to give gratuitous advice to many who can afford to pay, I would suggest that not only the lawyers, but also the chemists, dispensers, &c., and all down to the butchers and bakers of the hospital, should supply gratuitously, so that we might then have real charities instead of mere make-believes—*i.e.*, institutions where all the supernumeraries and subordinates are well paid, and the Medical officers, who are the chief officials and the very life and soul of the institution, receive—nothing.

I am, sir, your obedient servant,
M. B.

Medical News.

The Adulteration of Food Act.—The local Boards and Vestries of the parishes and districts within the metropolis have now, with two exceptions, complied with the provisions of the Adulteration of Food Act, by the appointment of official analysts. The Act gives the local authorities the option of making the appointment by fixed salaries, by allowances for each analysis, or partly by salary and partly by allowance ; and all these alternatives have been adopted by the various Boards. In Mile-end Old Town Dr. Corner, the Medical Officer of Health, has been appointed analyst, the question of salary being left in abeyance. In St. Pancras Dr. Stevens has been nominated. In Hackney Dr. Tripe, the Medical Officer, has been elected, the point of salary being left open for future consideration. In St. George's, Hanover Square, and Chelsea, it has also been resolved to include the office of analyst in the duties of officer of health. The Whitechapel Board have appointed Dr. Meymott Tidy, Professor of Chymistry at the London Hospital, at a fee of one guinea for the first 100 analyses, and a decreasing scale for cases beyond that number. Dr. Hardwicke has been elected for Paddington, Dr. Vinen for St. Olave, Dr. Muter for Wandsworth, and in St. Saviour's the office was voluntarily undertaken by the Medical Officer of Health. In Poplar the appointment has been given to Dr. Woodforde, one of the Medical Officers of Health, payment being made for each analysis on a fixed scale. Dr. Letheby has been appointed analyst for the City ; Dr. Bernays, Professor of Chymistry at St. Thomas's Hospital, has been appointed for Camberwell, Dr. Whitmore for Marylebone, Dr. Pavey for St. Luke's, Dr. Rogers for Limehouse, Dr. Muter for Lambeth and St. George's, Southwark. With three exceptions the local authorities of each district have elected their own Medical Officers of Health as analysts, and in Whitechapel the office was refused by Dr. Liddle, the Medical Officer, on the ground that Medical Officers were generally not competent to undertake the duties contemplated by the Act.

The Hospital Sunday Movement.—Nottingham has just held its Hospital Sunday, and the collections at places of worship realised about £850, to which must be added £150 contributed by the working men on the previous Saturday.

Native Guano.—It is stated upon authority that one result of the trial of native guano at the Royal Botanical Gardens at Potsdam in the yield of such products as potatoes, cabbage, turnips, carrots, and beans was, with a supply of 14 cwt. per acre, a much higher one than that obtained on similar soil with stable manure ; the potatoes more especially were all compact, large, smooth, and sound. Its application to forced fruit, particularly pine-apples, strawberries, cherries, plums, and grapes, an addition of fifteen parts native guano yielded very remarkable results.

Society for Relief of Widows and Orphans of Medical Men.—At the recent Quarterly Court of Directors, under the Presidency of Dr. Burrows, F.R.S., fifty-five widows and thirty-four children applied for assistance from the funds of the Society. A sum of £1,218 10s. was voted to be divided according to the wants of the respective applicants. The expenses for the quarter amounted to £57 17s. 4d. A legacy of £100, duty free, was announced as having been received from the executors of Martin Ware, Esq., late President. The death of R. Strong Eyles, Esq., one of the treasurers, was reported by the secretary.

Apothecaries' Hall of London.—At a court of examiners, held on Jan. 30, the following gentlemen, having passed the necessary examinations, received the L.S.A. diploma, viz. :—Messrs. William James Cole, of Westbourne Villas, Harrow Road ; Maurice Smelt Duke, of 321 Clapham Road ; Thomas Loane, of 1 Dock Street, Whitechapel ; Gerald Crécy Parnell, of Sussex Place, Regent's Park ; Evan Powell, of Bridgend, South Wales ; and Charles Wills, of Richmond, Surrey.

Royal College of Physicians of London.—On January 30th the following gentlemen, having passed the required examinations, were admitted as Members :—William Williams, M.D. Queen's University Ireland, Bennarfawr ; Norman Moore, M.B. Cambridge, St. Bartholomew's Hospital ; John Penn Hartree, M.B. Cambridge, 27 Grosvenor Street. The following gentleman was at the same time admitted Licentiate :—John Clague, Castletown, Isle of Man.

Last week, at the Bloomsbury County Court, an action was brought against Dr. Hill, Medical Officer of St. Pancras Workhouse, to recover £50 damages on behalf of Sarah Willding, an aged woman, whom it was alleged he had illegally detained in the workhouse as an imbecile when she was in a fit state to go out, and wished to do so. The jury, after hearing the plaintiff's evidence, as far as she was able to make herself intelligible, and also the evidence of Mr. Pearse and Mr. Robson, two of the Guardians who supported her case, were asked by the judge whether they felt able to form an opinion without hearing the defence. They immediately said that, in their opinion, Dr. Hill had acted honestly and for the best. The judge expressed his concurrence in this view, and nonsuited the plaintiff on the technical ground that sufficient notice of action had not been given. A full report of the case appeared in the *Daily Chronicle*, and well illustrates the annoyances to which Medical men are exposed in the discharge of their duties.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this request.

All communications intended for insertion must bear the name and address of the writer; not necessarily for publication, but as a voucher of good faith.

SUBSCRIPTIONS IN THE UNITED STATES.—A correspondent has drawn our attention to the fact, that some of the houses in the United States are charging the enormous figure of 15 dollars per annum (more than £8) for supplying this Journal to different parts of the States. We beg, therefore, to state that we shall be happy to supply the same regularly, post free, per annum, if paid in advance, for considerably less than half this amount, viz., six and-a-half dollars (about £1 6s. 0d.), either direct from our offices in this country, or through our recognised agents in the United States.

NOTICE TO SUBSCRIBERS.—Subscribers who desire to avail themselves of the reduced tariff, by paying for the year in advance, must please send in their subscriptions before the end of the present month, otherwise the usual rate for credit will be charged.

DR. B. W., London.—The addition arrived too late for insertion in our last.

DR. M., London.—The alteration has been attended to, and the copies forwarded in the regular course.

THE FITZROY AND BESSEMER STEEL COMPANY.—We have been requested to draw attention to the opportunities which this Company, just started, affords for profitable investment. As the prospectus is so full, and the objects are so clearly set forth in our advertising columns, our readers will be able to form their own judgment upon a subject which does not come within our province to give an opinion either for or against.

HELIOTYPE.—We have before us a neat little work describing and illustrating what this new process really is. It is well-known by authors and publishers that wood engraving is a most expensive luxury ; even such small engravings as frequently appear in this journal, illustrative of various diseases, run into considerable sums, we, therefore, welcome any legitimate attempt to lessen the expense, provided it be not at the cost of efficiency. The heliotype process is simplicity itself, it is neither more nor less than a photograph of the original drawing or sketch, printed in printer's ink at an ordinary printing press. Bichromate of potash, alum, and gelatine being the principal chemical substances employed in production. There have been a good many processes introduced of late, such as graphotype, Zincotype, autotype, &c., all of which are more or less failures, whether the heliotype will prove the success its promoters anticipate, remains to be seen, certainly the specimens before us are very excellent, and if they are not "got up for the occasion," they bid fair to establish a good reputation.

W. BATHURST WOODMAN, M.D., Hon. Sec.

6 Christopher Street, Finsbury Square, E.C.

DISPENSERS.—WANTED, a DISPENSER for Service at one of Her Majesty's Naval Hospitals possessing the major qualification of the Pharmaceutical Society. Age not less than 20, nor more than 25 years. Particulars regarding this Appointment, and copies of the new Regulations, may be obtained on application at the Medical Department of the Navy, Admiralty, Somerset House, W.C.

27th January, 1873.

SLIGO UNION—SLIGO DISPENSARY.

THE BOARD OF GUARDIANS having fixed the Salary of Apothecary at £80 per annum, the Dispensary Committee will proceed to elect a qualified APOTHECARY, on the 14th day of February, at 12 o'clock, at the above-named Salary. Candidates are required to produce their Testimonials on the day of Election. Personal attendance desirable.

DANIEL MACGILL, Hon. Sec.

31st January, 1873.

APOTHECARY ESTABLISHMENT FOR SALE.

TO be SOLD by PRIVATE CONTRACT, the INTEREST of the REPRESENTATIVES of the late H. P. Smith, Esq., L.A.H., in that Shop and Premises in the main street of the town of Strabane, in which the business of an apothecary has been successfully and extensively carried on for a great many years. The business has been conducted since the death of Mr. Smith by his Representative, and is at present in a flourishing condition. The receipts and sales of the business for several years past have averaged a sum exceeding £600 each year.

This is the only apothecary establishment in Strabane, a town of 5,000 inhabitants, 13 miles distant from Derry, and surrounded by a populous and rich district of country.

The stock of medicines at present on hand is large, and the shop fixtures are excellent, being almost as good as new.

The premises are held by lease for 30 years from the 1st November, 1866.

Proposals by intending purchasers will be received by the undersigned up to the 1st of March next.

Strabane, 28th Jan., 1873. THOMAS LYLE, J.P.

THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.

Patron:—H.R.H THE PRINCE OF WALES.

This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develope the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £35 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote.

Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c., can be had at the office,

40 MOLESWORTH STREET, DUBLIN,
W. O'NEILL, Secretary.

DUNFANAGHY UNION, CROSSROADS DISPENSARY DISTRICT.

MEDICAL OFFICER WANTED.

THE COMMITTEE of MANAGEMENT of the CROSSROADS DISPENSARY will, at their Meeting on WEDNESDAY, the 5th of February, at 12 o'clock, in accordance with the sealed order of the Local Government Board, proceed to elect a SECOND MEDICAL OFFICER for said District, at a Salary of £100 per annum, exclusive of Vaccination and Registration fees.

Testimonials as to character and competency to be lodged with the Honorary Secretary, before the day of Election.

Personal attendance of Candidates necessary, and the person elected must reside at Falcaragh, or immediate neighbourhood.

Application to be made to the,

Rev. V. P. GRIFFITH, Hon. Sec.

Falcaragh, Letterkenny, January 16th, 1873.

The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements, from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

The scale of charges is as follows:—

	£	s.	d.
Seven lines and under	£0	4	0
Per line afterwards	0	0	6
One quarter page	1	5	0
Half-page	2	10	0
One do.	5	0	0

When advertisements are given for a series of insertions, a very considerable reduction from the above scale is made.

☞ Advertisements for Insertion in this Journal must be at the OFFICE, on SATURDAY, by Two o'Clock.

ASTHMA—SLADE'S ANTI-ASTHMATIC CIGARETTES after having been submitted to many careful trials, are found to be safe, efficient, and agreeable, are now daily prescribed by the most eminent Physicians treatment (specially) ASTHMA, and other Bronchial and Pulmonary Affections. In Bottles, at 2s. 9d., 4s. 6d., and 11s.

Prepared by THOMAS SLADE, Pharmacian,
118 LONG ACRE, LONDON.

A liberal discount allowed to the Wholesale Houses, the Profession, Hospitals, Infirmaries, &c. Wholesale Provincial Agents:—Bewley & Draper, Dublin; Raimes & Co., Edinburgh, Liverpool, and York; Jewsbury & Brown, Manchester: Charles Britten, and Banks & Richards, Birmingham.

Prompt attention to Country Orders. Terms, cash on receipt of goods, and 1s. each for package. Goods delivered free within 7 miles P.O.O. to be made payable to I. ISAACS and Co., at the Post-office Tottenham court road.—Bankers, London and Westminster Bank.

Established nearly 100 years

AMSTERDAM EXHIBITION, 1869.

THE GRAND DIPLOMA OF HONOUR, being the first prize and superior to the Gold Medal.

LIEBIG COMPANY'S EXTRACT OF MEAT.

Paris Exhibition, 1867. Two Gold Medals; Havre Exhibition, 1868, The Gold Medal.—Only sort warranted perfect and genuine by Baron LIEBIG, the Inventor.—"A success and a boon." MEDICAL PRESS AND CIRCULAR.—One pint of delicious beef-tea for 2½d., which costs 1s. if made from fresh meat. Cheapest and finest flavoured "stock" for soups, &c.

CAUTION.—Require Baron LIEBIG'S signatore upon every jar. Sold by all Italian Warehousemen, Grocers, Chemists, and Ship's Store Dealers; all Wholesale Houses; and of LIEBIG'S EXTRACT OF MEAT COMPANY (Limited), 43 Mark lane, E.C.

NOTICE.—Various chemical analyses have been published, purporting to show a fraction more of moisture to exist in the Company's Extract than in some imitation sorts. It is extremely easy to evaporate the water almost to any extent, but it is quite as certain that the fine meaty flavour which distinguishes the Company's Extract from all others would be destroyed if the concentration of the Extract were carried beyond a certain degree. Beef-tea made from Liebig Company's Extract, with *boiling hot water*, will be found to be greatly superior in flavour, strength, and clearness to any other sort. This explains the universal preference it obtains in the market.

This Extract is supplied to the British, French, Prussian, Russian, and other Governments.

JAMES'S FEVER POWDER.

4s. 6d. PER BOTTLE, PACKETS 2s. 9d. EACH.

PREPARED and sold by J. L. KIDDLE, 31 Hunter street, Brunswick square, London.

This preparation has been so extensively employed by the Faculty and its merits so universally acknowledged by the public at large, as to render all further remarks on the part of the Proprietor unnecessary.

To be had of all Wholesale Druggists.

CELENTA EGYPTA.

THIS exceedingly digestible restorative, composed of prepared Lentils and other cereals, is strongly recommended for use in convalescence from sickness, and for Invalids generally, as an excellent Substitute for Animal Food. A somewhat similar article, sold under the name of Reve enta, is well known. The CELENTA EGYPTA is but about half the price; and as it contains, weight for weight, four times the nutrient power of beef, its relative value is easily calculated.

Sold in 1s. 6d. Tins, by W. HILL and SON, Biscuit Bakers to the Queen. Sample forwarded gratis.

ENTIRE WHEATEN NURSERY BISCUITS

differ from all other, inasmuch as, the bran being ground to an impalpable powder, they contain the whole constituents of the grain. The earthy phosphates, so essential to the proper formation of the bones and teeth, not being removed, renders these Biscuits particularly useful to Children.

Sold at 10d. per lb., by W. HILL and SON, 60 Bishopsgate Street, and 3 Albert Mansions, Victoria St., S.W. Samples forwarded gratis.

RED HEART RUM.

CELEBRATED FOR ITS GREAT AGE, SOFTNESS, and PURITY.

It was specially supplied to the Sick and Wounded during the late War, and is strongly recommended in cases of

CHOLERA, DIARRHŒA, SEVERE COLD, &c.

Price 42s. per doz., bottles and case included. Samples can be had at 3s. 9d. per bottle.

Agent—J. G Turney, New Bond street, London.

AERATED LITHIA WATER.—Messrs. BLAKE SANDFORD, and BLAKE are prepared to supply the LITHIA WATERS (of which they were the original manufacturers under Dr. GARROD'S instruction) of any strength prescribed by the Profession for special cases. Those in constant use contain two grains and five grains in each bottle, either by itself or combined with BICARBONATE of POTASH or PHOSPHATE of AMMONIA. Also, POTASH, CITRATE of POTASH, SODA, SELTZER, VICHY, and MINERAL-ACID WATERS, as usual.—BLAKE, SANDFORD, and BLAKE, Pharmaceutical Chemists, 47 PICCADILLY

T. and H. SMITH'S

CODEIA LOZENGES.

THESE LOZENGES have a remarkable effect in allaying Cough and Irritation of the Throat and Chest.

Prepared only by T. and H. SMITH and CO., 21 Duke street, Edinburgh and 12 Worship street, London; and to be had of any Chemist and Druggist, in Boxes at 1s. 1½d. and 2s. 9d. each.

TO PUBLIC LIBRARIES, &c.

THE BACK VOLUMES OF "THE MEDICAL PRESS," for the years 1839 to 1865 inclusive, have been bound in cloth, and can be supplied at 10s. per volume (one year) nett cash, at either of the publishing offices of the Journal, in London, Dublin or Edinburgh

The Medical Press & Circular.

ON ANTHRACOSIS (COAL-MINER'S LUNG, BLACK SPIT).

By Thos. Whiteside Hime, A.B., M.B., &c.

Lecturer in the Sheffield School of Medicine, and Medical Officer to the Hospital for Women, &c.

The terrible fact that for every million of tons of coal raised in England, from 1851-59, cost 2·99 lives, in Prussia 2, in itself conveys but a feeble picture of the risks to which coal-miners are exposed. No one, with human feelings, who has personally inspected a coal-mine, could avoid being struck by the degrading nature of the work, equally for body and mind. The effect of the darkness, danger and damp, combined with dirt, cold, and more or less, complete isolation, must produce a depressing effect on animal, as well as vegetable, vitality. A cavern which shuts out the sun's rays only by a few feet of wall, is sufficiently uncomfortable to make a sojourn of a couple of hours objectionable, owing to its chilly atmosphere, damp surface, and cheerless aspect. What must be the effect of a lifetime spent to a great extent in such a place, many hundred yards under the surface? The walls of coal-mines are frequently very damp, water issuing from them, and the floor, in drops, or streams. The woodwork and fossil remains are thus saturated, and chemical decomposition induced, which must vitiate the air seriously, by the absorption of oxygen, and in other ways. Where the disadvantages of damp are absent, equally injurious influences may be called into action by the dust, on the effects of which some observations may be of interest. It is clear that, in considering the effects of coal-dust, it would be improper to leave out of sight, as has been usually done, the other depressing influences to which the miner is subjected, and a few of which have been alluded to, as these render him much more susceptible to other debilitating causes, by lowering his power of resistance. It is unfortunate that statistical enquiries, which are in this matter so important, have been but scanty, although the materials are abundant and not difficult to be obtained by Medical men in *mining* districts, and managers of mines.

The dust of mineral coal, as distinguished from wood (charcoal), presents differences of appearance, most important as bearing on their effects. The former, when examined microscopically, is roundish, or polygonal, and offers but few or no sharp points; the latter, on the contrary, exhibits very sharp projections, and minute particles of woody fibre are not infrequently found mixed up with it. Various substances are found existing in the dust, but none of these present any comparison with the sharp, angular flint-dust, which may exist to the amount of 20 per cent., or even 30 per cent. The nature of the influence which exposure to coal-dust exercises has been most variously estimated and characterised by different writers, indeed there is no subject about which it can be said that "doctors differ" more completely. For, whereas, some writers regard coal-dust as one of the deadliest agents, others consider it to be merely not free from danger, and some even as of therapeutic value.

Of the various organs which may be injuriously affected by the presence of dust in the air, there is none so frequently involved as the organs of respiration, and there is none upon which the action of dust produces effects so injurious to the general health.

Metallic dust is more injurious than any other kind, such for example as ivory, tobacco, &c. The air in the workshops inhaled by some workmen is positively thick with dust, and most difficult for persons to inhale, who are used to a purer medium. For a longer or shorter portion of the day, amount into at least fifty-four hours per week at present, the workman introduces with each inhalation a quantity of dust, which penetrates into the respiratory organs, more or less extensively, thus producing what in its initial stage is simply the result of local mechanical irritation, but subsequently presents characters usually as defined as those offered by many so-called specific diseases. The effects of an atmosphere thus charged are, strange to say, sometimes not at all injurious, and examples of fine, robust men are not wanting among persons exposed to such danger; but it cannot be doubted that dust (in combination with other influences, *possibly*) induces a predisposition to diseases of the respiratory organs. As before mentioned statistics are lacking on this subject, and those at our disposal are almost entirely from hospitals, into which those labouring from the slighter forms of disease induced by dust never gain admisssion, so that we may fairly assume that our statistics represent results less unfavourable than they would appear if we had larger data for consideration. Among the working classes, as a whole, diseases of the respiratory organs amount to 35 per cent. of all internal diseases (Oesterlen); as many as 50, 55, and even 60 per cent., of all such cases occur among those who work at dusty trades (Hirt). In spite of the indubitable evidence which can be adduced, there are persons who deny that dust does penetrate at all any length into the respiratory organs. The views of one of the most distinguished supporters of this theory, Prof. Cl. Bernard, deserve more particular mention, from the confidence to which his skill as an experimental enquirer entitles him. In the "Lecons sur les effets des Substances Toxiques et Medicamenteuses," published in 1857, by Prof. Bernard, he describes an experiment performed before his class at the College de France. He kept a rabbit with its head confined in a bladder containing a quantity of coal-dust (*poudre de charbon*). It was so arranged that the animal could run about with the bladder, in its movements agitating the dust, and thus causing more of it to float in the confined atmosphere it respired. An animal killed after *several days'* treatment in this manner had no black coloration of the lungs. Particles of dust were to be found in the nasal fossæ, but none had penetrated even as far as the larynx. The dust was stated to have been so strained out of the air in the nose and upper part of the respiratory passages, that none reached the pulmonary vesicles. The vibratory ciliæ of the nasal fossæ were stated to be able thus to arrest completely the passage of dust into the lungs. It was further argued that the black coloration of the lungs is not confined to coal-miners, occurring also among other workmen. Now, with regard to the action of the ciliæ it is very probable that, in a healthy subject, unaccustomed to breathe a dusty amosphere, they could arrest all particles which might *come in contact* with them; or that, where the dust is very fine some of it would be carried off by the outward current said to be excited in the air of the respiratory tract which is under the influence of the ciliary movements in the outward direction. But this will not apply to the dust contained in the inward current of inspired air, which is vastly larger and more powerful than the ciliary current. The filtering influence of the ciliæ on it must be *nil*. But facts must ever be more convincing than theories, and it is beyond all doubt that particles of dust, both metallic and non-metallic, may, and generally do, exist in the lungs in cases of diseases of these organs in workers at dusty trades. Recent experiments prove too, that it is far from improbable that solid particles may effect an entry even into the circulation, from without, and thus reach the tissues in which they are found embedded. Whatever may have been the result of experiments on rabbits after three days' exposure, as above stated, there is no doubt that solid particles have been found in "miner's-lung," and in the lungs of others long exposed to dust. The following observations relative to the presence of dust in the respiratory organs are noteworthy.

(To be continued.)

◆

A STORY OF WATERLOO.

(Compiled by C. A. Gordon, M.D., C.B., &c., &c.)

Further Particulars.

A copy of the Medical Press and Circular containing my remarks on the surgical arrangements connected with the battle of Waterloo was sent to the Chaplain-General, from whose interesting "story" of that battle the particulars were gathered. The Chaplain-General, one of the very few now living of those who where present in that action, has most kindly communicated to me further particulars on the same subject, and I feel sure that, coming as they do from so high and competent an authority, they will have a special interest, not only to army Medical officers, but to military also. Mr. Gleig does me the honour to write as follows:—

"I am much obliged to you for sending me your paper on the surgical details of the battle of Waterloo. It is much to be regretted that the chiefs of the Medical department did not keep a more faithful record than they seem to have done, of the appliances at their command during the great war of the French revolution. I will tell you in a few words as much as I can recollect about these matters.

"There followed the army what was called a waggon train, distributed into divisions, one or more of which was in attendance on each division of the army. I believe that the waggons were used to carry light stores of various kinds when the army was advancing, but of that I cannot speak with perfect certainty. This, however, I do know—that when the army, or any part of it, was engaged, these waggons made their appearance at every lull in the action, and took up a position upon the main road. The wounded were lifted into them by their comrades, sometimes on blankets, sometimes by mere strength of arm, and placed upon the seats, which ran along each side, and at the rear. The waggons were spring waggons, and canopied over, but they were few in number, and only the worst cases were allowed to be put into them, the rest made their way to the rear as best as they could, and a serious diminution of strength in the line was occasioned by the escorts that attended them. The officers, of course, did their best to throw all this burden upon the bandsmen, though it was not very easy to hinder a comrade from going off with his wounded friend.

"Besides the waggon train bullock cars were used if the wounded were very numerous, but they were awful instruments of torture, being without springs, and moving upon axles that revolved.

"Each regimental surgeon had his panniers slung across the back of a mule, which contained the materials necessary for dressing wounds upon the field, where many an amputation took place.

"Of the hospitals I can speak from experience. They were established in farm houses, and made as comfortable as circumstances would allow. The wounded and sick lay upon ticking stuffed with straw or ferns. They had plenty of clean blankets, but sheets were scarce. Nothing could exceed the tenderness and attention of the Medical officers. I have known them sit up two, even three nights together, extracting bullets, amputating limbs, and dressing wounds. I have often wondered since how they were able to stand the fatigue.

"Nurses we had none, but the hospital orderlies were very kind-hearted fellows, and worked like their masters, the doctors, indefatigably.

"The great Duke was, I need not tell you, a man who never made a display of his feelings, but whatever was necessary for the comfort of the sick and wounded, he did his best to provide; and in Sir James Macgregor, the head of the Medical department, he had a first rate staff officer.

"This is a very rough outline of a picture, the details of which I am afraid there are very few now alive, capable of filling up; but if there be any points on which you think I can give you information, I beg that you will state them, and I will do my best to meet your wishes."

I believe that it would be interesting to collect simil particulars in regard to the surgical details during t wars in which England was engaged in the 18th centu and the great struggle in the Peninsula at the beginni of the present. The contrast between them, and t arrangements now made for the sick and wounded in w would show the extent to which the functions of t Medical service have become developed, the vast amou of benefit that department confers upon those who are stricken down on service, whether by wounds or by sickness, and the still greater benefits it is capable of conferring, when the same powers of action are accorded to Medical chiefs in all that concerns their special sphere during service in the field, as are accorded to other responsible officers in regard to their several spheres. I observe that this improvement has lately been introduced into the Medical services of the German and Italian armies, doubtless as a result of experience gained by the former in the late war in France.

◆

THE ABSORPTION OF TOBACCO SMOKE.

(Notes from Dr. Le Bon, and others.)

By Charles R. Drysdale, M.D.,
Senior Physician to the Metropolitan Free Hospital of London.

Every one knows that the chief injurious effects of tobacco are due to the nicotine contained in it. Hence, the importance of considering whether tobacco smoke contains nicotine. Now, Melseus collected from 4,500 grammes of tobacco smoke passed through water, 30 grammes of nicotine. Dr. Le Bon in the *Giornale Veneto di Scienze Mediche S.*, iii, 1872, remarks that the fact of nicotine being absorbed by smokers is proved not only by the injurious effects on the organism, but also by other circumstances. The alkaloid is soluble in water and in the fluids of the mucous membranes; smoke condensed and mingled with water becomes easily absorbed. As to the quantity of nicotine absorbed in smoking, science has as yet nothing exact to mention, since this varies according to the kind of tobacco used and the circumstances under which it is used.

Besides nicotine, tobacco also contains ammonia in notable quantity, which is taken up by the mouth and lungs. When cigars are smoked the constituent parts of the tobacco are turned into the form of vapour. A part of the smoke spreads itself over the cool tobacco leaf near the mouth, another part comes in contact with the cool mucous membrane of the mouth, where it is condensed and absorbed. The rest is spread about in the air. The further the burning process of the cigar proceeds, the moister does the tobacco leaf become, the more smoke arrives at the mouth, and becomes absorbed, so that the end tastes bitter, and beginners feel sick from this fact when smoking a cigar to the end.

Hence, it seems that in the smoking of cigars, especially if smoked to the end, a very notable quantity of nicotine and other constituents of tobacco are absorbed, even when smoking takes place out of doors, and the smoker does not inhale the smoke into the lungs. If the smoking take place in closed rooms, then not only are nicotine and the other parts of the tobacco taken up in the mouth, but also with each breath a portion of the tobacco smoke contained in the air of the room. The quantity of injurious substance of course becomes the greater just in proportion as the room is smaller, and there are more smokers. A railway smoking carriage is, of course, the *ne plus ultra* of unwholesomeness in this respect.

Persons who indulge in the habit of first inhaling the smoke, and then expelling it by the nostrils and mouth, take up a much larger quantity of nicotine from the great absorption power of the lungs and other mucous membranes.

When pipes are smoked, even with short stems, there is much less injurious substance absorbed, because the smoke is absorbed in the cool tube, less of it arrives in the mouth, and, as is well known, is found among the ashes of the pipe. The longer the stem, the less of the constituents arrive at the mouth or lungs; hence, the advantage of long pipes, and especially of Turkish hookahs, when the smoke passes through water.

With regard to persons who, not themselves smoking, remain in chambers where smoking takes place, they cannot in any way escape the injurious effects of tobacco smoke. If they do not inhale so much injurious matter as the smoker himself, still they take in on each breath a quantity of the constituents of tobacco smoke mingled with air; and to such a degree that he or she who lives in such a room takes in more nicotine than a smoker does who smokes only in the open air.

Hence, it appears, that women who serve in public houses and cigar divans, are materially injured by a vice which their own sex is innocent of; and this fact may, perhaps, restrain some good-hearted male, who is quixotic enough not to care sufficiently for his own health.

It is now well known by the observations of Dr. Kostral in the Austrian State tobacco manufactory, that persons employed in tobacco manufacture are subjected to many diseases, especially in the case of young women and boys.

◆

The Medical Press
FORTNIGHTLY RETROSPECT
OF
MEDICINE, SURGERY, AND THE COLLATERAL SCIENCES.

> "The multiplicity of subjects with which the mind of the Medical man, who attempts to keep pace with the progress of his science is constantly occupied, renders it desirable that ideas which are intended to be of practical utility to him should be submitted to his grasp in the smallest compass and most defined form of which they are capable."

No. II.

N.B.—Authors are invited to send copies of their works, with such passages marked as they deem worthy of special notice in these Reports. All communications should be addressed to "The Editor of the *Medical Press Retrospect*," at either of the Offices of Medical Press and Circular.

(All rights in connection with these Reports are reserved.)

PHYSIOLOGY.

CIRCULATION.

Pettigrew, J. Bell.—"On the Physiology of the Circulation in Plants, in the Lower Animals, and in Man." *Edin. Med. Jl.*, July, 1872, *et seq.* Dr. Pettigrew's excellent papers will be noticed in abstract when completed.

RESPIRATION.

Ransome, Arthur.—"On the Mechanical Conditions of the Respiratory Movements in Man." *Proc. Roy. Soc.*, Nov., 1872. Analysed by Dr. Burdon Sanderson in *Med. Record*, Jan. 8.

M'Kendrick, John. G.—"An Apparatus for maintaining Artificial Respiration in Physiological Experiments." *Edin. Med. Jl.*, Jan.

DIGESTION.

Schiff.—"Experiments on Gastric Digestion." See Dr. Ferrier's analysis in *Medical Record*, Jan. 15th. Schiff finds that digestive power depends not on the mere quantity of the pepsine, but, in great measure, on the relative quantity of water and acid in the artificial infusion.

Schiff.—"Researches on the Pancreas." See Dr. Ferrier's analysis in the *Med. Record*, Jan. 15. Schiff injected fluid paraffin into the duct; this stops the secretion by becoming solid. The conclusion which he draws from his experiments is that a pancreas is not essential to the digestion of fat.

ABSORPTION.

Heubel.—"On the Relations of the Central Nervous System to Absorption." *Virchow's Archiv.*, Vol. 56.

Heubel finds that the cerebrum, optic thalami, optic lobes, and cerebellum, have no influence over absorption; but after destruction of the medulla and cord absorption ceases, a fact which he attributes to stoppage of the circulation. See Dr. Brunton's report in *Med. Record*, Jan. 15.

SECRETION.

Defresne.—"On the Biliary and Pancreatic Secretions in the Omnivora." *Acad. des Sci.*, Dec. 23, 1872.

Sinety, L. de.—"On the State of the Liver in Females during Lactation." *Acad. des Sci.*, Dec. 23, 1872. He says that it is fatty, but that the adipose substance is from centre to periphery, not from periphery to centre as in ordinary fatty liver.

INNERVATION.

Schiff.—"Paths of Conduction in the Spinal Cord." See Dr. Ferrier's able abstract in *Medical Record*, Jan. 15.

Vulpian, M. A.—"The Influence of Traumatic Lesions of Nerves on the Physiological Properties and Structure of Muscles." *Archiv. de Physiol.*, No. 9, 1872.

Ranvier.—"On the Fine Structure of the Elements of Peripheral Nerves, and the Physiology of these Nerves." *Soc. de Biol.*, Nov. 11, 1872.

REPRODUCTION.

Duncan, J. Matthews.—"Note of a Proof of the Free Intercommunication near the Chorionic Surface between different Parts of the System of Maternal Cells or Blood-Caverns of the Placenta, in the same and in different Cotyledons." *Edin. Med. Jl.*, Jan. Dr. Duncan is a firm adherent to the Hunterian doctrines as to the structure of the placenta, and he pronounces in favour of the Goodsirian view, viz., that the walls of the maternal cells are wholly composed of maternal tissues, the fœtal villi being encapsuled in maternal structure. A small globule of air incarcerated beneath the chorion in a perfectly fresh placenta may be hunted about by very slight pressure with the tip of the finger—a fact Dr. Duncan thinks susceptible of no other interpretation than that free intercommunication does exist.

MEDICINE.

MORBID STATES OF THE BLOOD.

Neumann.—"Case of Leukæmia with Disease of Spinal Cord." *Archiv. der Heilkunde*, Nov., 1872.

Rosenstein, S.—"Carbonate of Ammonia and Uræmia." *Virchow's Archiv.*, Vol. 56, Part 3, 1872.

GENERAL DISEASES.

Heyman, C.—"Contribution to the Study of Rheumatism." *Virchow's Archiv.*, Vol. 56, Part 3, 1872.

FEVERS.

Barbaste.—"Typhoid Fever; Suffocative Form." *Union Med.*, Dec. 7, 1872.

Wunderlich, C. A. V.—"Intestinal Hæmorrhage in Enteric Fever under the Cold Water Treatment." *Archiv. der Heilkunde*, Nov., 1872.

Dedat.—"Treatment of Intermittent Fevers by Subcutaneous Injections of Carbolic Acid." Dr. Dédat uses solutions of the strength of 1 of acid to 100 of water. Quoted *Lancet*, Jan 11.

Darby, Thomas.—"On the Late Epidemic of Small-Pox." *Med. Soc. Coll. Phys. Irel.*, Nov. 20, 1872. Of 231 patients treated by Dr. Darby in the Rathdown Hospital, 168 had the specific mark of previous vaccination, 13 had been revaccinated, in 15 vaccination was doubtful, 34 had not been vaccinated, and 1 had had a former attack of natural small-pox.

Geissler, A.—"Remarks on Small-Pox and Vaccination." *Archiv. der Heilkunde*, Nov., 1872.

Netter, A.—"Variola and Vaccination." *Tribune Med.*, Dec. 29, 1872.

DISEASES OF THE ORGANS OF CIRCULATION.

Laseque, C.—"Cardiac Intermittence." *Archiv. Gen. de Med.*, Dec., 1872.

Gairdner.—"Case of Tubercular Pericarditis; Paracentesis Pericardii." *Glasgow Med. Journ.*, Nov., 1872.

Peacock, Thomas.—"Case of Four Aortic Valves." *Path. Soc. Lond.*, Jan. 7.

Carter, Charles.—"Heart with Supernumerary Pulmonary Valve." *Path. Soc. Lond.*, Jan. 18.

DISEASES OF THE ORGANS OF RESPIRATION.

Brown-Sequard.—"On the Production of Apnœa and on its Causes." *Soc. de Biol.*, Nov. 11, 1872.

Cadet, S.—"Treatment of Diphtheria." *Lo Sperimentale*, Nov., 1872.

Giacchi, O.—"Nature and Treatment of Diphtheria." *Lo Sperimentale*, Nov., 1872.

Heubner.—"Two Rare Complications of Diphtheria." *Jahr. der Kinderheilkunde*, Dec., 1872.

Morelli, C., et Nesti, L.—"Clinical History of Diphtheria in the City of Florence during 1862-72." *Lo Sperimentale*, Nov. et Déc., 1872.

Dubone.—"Successful Employment of Tannic Acid in Pleurisy, especially Chronic Purulent Pleurisy." *Gaz. Hebd. de Med.*, Dec. 27, 1872; quoted *Lancet*, Jan. 11.

Foot, Arthur Wynne.—"Empyema of Left Side opening spontaneously in the Left Lumbar Region—Recovery with Lumbo-Pleural Fistula." *Dub. Med. Journ.*, Jan. Dr. Foot, in the same journal, gives the details of another case of empyema of the left side, which passed downwards behind the internal arched ligament into the left psoas muscle, and thence into the vertebral canal; lymph or pus was deposited upon the posterior surface of the Theca Vertebralis.

Foot, Arthur Wynne.—In the *Dub. Med. Journ.*, Jan., Dr. Foot relates two cases of circumscribed pulmonary gangrene from hæmorrhagic infarction, the result of submersion; the hæmoptysis was frequent; both cases recovered.

Kelly, J.—"Phthisis simulated by Pneumonia of the Upper Lobes." *Indian Med. Gazette*, Dec. 2, 1872.

Cheron, Jules.—"On the Arrest of Destruction of the Lung in Chronic Phthisis by the Inhalation of Vapours of Oxygenated Essences." *Gaz. Hebd. de Med. et Chir.*, Dec. 30, 1872.

Smith, Robert.—"Consumption in the Highlands and Islands to the West of Scotland with reference to the Immunity claimed for these Districts while the People remain at Home." *Edin. Med. Journ.*, Jan.

Zuradelli, C.—"The Various Forms of Pulmonary Phthisis." *Ann. Univ. di Medicina*, Dec., 1872.

DISEASES OF THE ALIMENTARY CANAL.

Platt, W. H.—"Case of Intestinal Obstruction with Hernia through the Peritoneum." *Lancet*, Jan. 11. This is a singularly interesting case, Dr. Richardson in his remarks thereon says—"The immediate cessation of vomiting that followed upon this operation (tapping), the complete removal of distension, and the success of the simple and ingenious method devised by Dr. Platt, by which he was enabled to draw off through the canulæ forty ounces of fæcal fluid in a few hours without pain or injury, are all facts worthy of remembrance. In another similar case I should certainly be inclined to perform the operation at a much earlier period. I feel assured that in the case related it prolonged life; and, as in this case and in many similar the actual cause of death is probably the depression arising from the absorption of decomposing fæcal fluids and gases of decomposition, it must be sound practice to endeavour to gain time by diverting such absorption."

Hutchison, G. Wright.—"Extraordinary Case of Pin-Vomiting." The patient, a nursemaid, æt. 20, vomited in all seventy-five pins, besides which thirteen needles made their way out at different parts of the body, nine of them issuing behind the left ear, two in the front of the right forearm, and two from the left nostril. The history of the case is indeed almost incredible, but is well authenticated. *Lancet*, Jan. 18.

HODDER, E. M.—"Transfusion of Milk in Cholera" is the subject of a most important letter in the *Practitioner*, Jan.

DISEASES OF THE LIVER.

PEACOCK, THOMAS.—"Liver with the Portal Vein blocked by a Clot." *Path. Soc. Lond.*, Jan. 7.

STEWART, T. GRAINGER.—"Case of Dilatation of the Bile Ducts followed by Abscess of the Liver." *Edin. Med. Journ.*, Jan. This case was remarkable inasmuch as there was no history pointing to previous obstruction, and there was no constriction at the time of death. Dr. Stewart puts forward the suggestion that the dilatation was either congenital or the result of a gradual process not yet described.

DISEASES OF THE KIDNEYS.

PERL, L.—"Compensatory Hypertrophy of the Kidneys." *Virchow's Archiv.*, Vol. 56, Part 3, 1872.

DONKIN, ARTHUR SCOTT.—"Further Observations on the Skim-Milk Treatment of Diabetes Mellitus." *Lancet*, Jan. 11 and 18.

BRADBURY, J. B.—"Case of Diabetes Insipidus—Rapid Improvement under the Use of Valerian." *Lancet*, Jan. 11.

DISEASES OF THE NERVOUS SYSTEM.

ANSTIE, F. E., continues his interesting lectures "On Diseases of the Nervous System." *Lancet*, Jan. 11.

BEALE, L. S.—"Case of Red Softening of the Brain." Reported *Lancet*, Jan. 18.

BECOULET ET GIRAND.—"Note on the Cysticercus of the Brain." *Ann. Med. Psychol.*, Nov., 1872.

GRIMSHAW, THOMAS W.—"Aneurism of the Basilar Artery." *Path. Soc. Dublin*, Jan 11.

JACKSON, J. HUGHLINGS.—"On the Anatomical and Physiological Localisation of Movements in the Brain." *Lancet*, Jan. 18.

PIERRET, M.—"Note on a Case of Peripheric Atrophy of the Cerebellum with Concomitant Lesion of the Olfactory Bulbs." *Archiv. de Physiol.*, No. 9, 1872.

SMITH, EUSTACE.—"Case of Large Sarcomatous Tumour of the Brain in a Boy." *Lancet*, Jan. 11. In this case there was no sign of recent inflammation, and still the temperature was greatly heightened. Immediately before death the increase in the heat of the body was rapid and extreme. It was not until within forty-eight hours of death that there was any sign of impairment of the intellect.

TILING, T.—"Case of Partial Sclerosis of the Brain." *St. Petersb. Med. Zeitschrift*, Vol. 2, Part 2, 1872.

WERNER, A.—"Injury of the Frontal Lobe of the Left Cerebral Hemisphere in relation to the Pathology of Injuries of the Brain and Localisation of the Cerebral Functions." *Virchow's Archiv.*, Vol. 56, Part 3, 1872.

ALLBUTT S. CLIFFORD.—"On Migraine." *Practitioner*, Jan. Dr. Allbutt says that the more he sees of migraine the more convinced he is that it is a neuralgia in point of origin and affinity, and the more convinced is he also of the essential part played in it by the abdominal viscera. He concludes a very able paper by contending that "migraine is not a mere trigeminal pain with 'cerebral' vomiting, but that it is a complex affection in which abdominal and cephalic disorder go hand in hand, and in which the treatment addressed to the former set of morbid events is at least as important as that which is addressed to the latter."

ANSTIE, F. E.—In a not less interesting and able paper in the same journal, Dr. Anstie replies to Dr. Allbutt. He believes that "were appropriate treatment addressed to the nervous system at an early stage of migraine we should not have to trouble ourselves directly with the management of abdominal complications at all, or, at least, that the number of examples in which these complications would become a subject of special necessary attention would be indefinitely reduced."

ECHEVERRIA.—"Effects of Bromides in Epilepsy." *Philadelphia Med. Times*, Dec. 16, 1872. See Dr. Ringer's analysis in *Med. Record*, Jan. 15.

DISEASES OF THE SKIN.

MONTI, A.—"On the Affections of Mucous Membranes in Acute Exanthemata." *Jahr. der Kinderheilkunde*, Dec., 1872.

SURGERY.

PROCESSES OF LOCAL DISEASES.

RICHARDSON, B. WILLS.—"Intimate Mixture of Cancer with Enchondroma." *Dub. Med. Jl.*, Jan.

EFFECTS OF POISONS GENERATED BY DISEASED ANIMALS.

ALLBUTT, CLIFFORD.—"Pathology of Hydrophobia." *Trans. Path. Soc.*, Vol. 28, 1872.

VENEREAL DISEASE.

"Etiology of Gonorrhœa and Syphilis." Leading article, *Lancet*, Jan. 11.

BONADEI, ULISSE.—"Four Cases of Constitutional Syphilis cured by Hypodermic Injections of Calomel." *Giornale Italiano delle Malattie Veneræ e delle Pelle*, Dec., 1872.

PICO, SANTE.—Three similar cases in the same journal.

VIDAL, E.—"Contribution to the Study of Constitutional Syphilis resulting from the Soft Chancre." *Union Med.*, Dec. 17, 1872.

DROU, A.—"Epidermic Grafts on a Syphilitic Chancre." *Lyon Med.*, Dec. 22, 1872.

DISEASES AND INJURIES OF PERIOSTEUM AND BONE.

PHILIPEAUX, J. M.—"Experiments showing that Osseous Particles developed in Transplanted Shreds of Periosteum are spontaneously absorbed and disappear at the end of a certain time." *Soc. de Biol.*, Nov. 4, 1872.

JOINTS.

BUTCHER, RICHARD.—"Excision of the Knee-Joint." *Dub. Med. Journ.* The rules inculcated by Mr. Butcher should be studied carefully by every practical surgeon.

MCDONNELL, ROBERT.—"Fatal Case from the Use of the Aspirator in Chronic Effusion into the Knee-Joint." *Irish Hosp. Gazette*, Jan. 15.

ORGANS OF CIRCULATION.

BUTCHER, RICHARD.—"Ligature of the Iliac Artery for the Cure of Inguinal Aneurism." *Dub. Med. Journ.*, Jan. The aneurism was the size of a melon, the patient's age was seventy-six, the result of the operation was successful although life was nearly lost by the inflammation of the sac of the aneurism which involved the thigh.

COLLES, WILLIAM.—"On Torsion as a means of arresting Hæmorrhage." *Irish Hosp. Gazette*, Jan. 15. Dr. Colles is fully in favour of torsion. He throws out what seems to us a most useful suggestion, viz., that in cases where we wish to arrest the current of blood in the continuity of the vessel, as in operating for aneurism, "after laying bare the artery, we might catch it transversely in a narrow forceps and press it so as to divide the inner layers and then push them away from the outer coat upwards and also downwards, leaving the outer coat *in situ* and to contract."

CARTER, W. G.—"Nævi Materni." *Lancet*, Jan. 18. Mr. Carter speaks in favour of electrolysis as a mode of treatment and refers to Dr. P. C. Smyly's instructions, viz., to injure the skin as little as possible, and to work with the point of the needle well under it.

INJURIES OF THE HEAD.

VOGT, P.—"Contributions to the Symtomatology and Treatment of Complicated Injuries of the Skull." *Deutsche Zeitschrift für Chirurgie*, Vol. 2, Part 2, 1872.

INJURIES AND DISEASES OF THE SPINE.

BENNETT, E. W.—"United Fracture of the Spine." *Path. Soc. Dub.*, Jan. 15.

INJURIES AND DISEASES OF THE EYE.

RICHARDSON, B. WILLS.—"Case Illustrative of the Mydriatic Treatment of Iritis." *Irish Hosp. Gazette*, Jan. 15.

ROBERTSON, ARGYLL.—"Rupture of the Choroid." *Med. Chir. Soc. Edin.*, July 3, 1872.

WATSON, W. SPENCER.—"Diagnosis of Periostitis in the Orbit." *Practitioner*, Jan.

INJURIES AND DISEASES OF THE EAR.

RENANT, M. F.—"Note on a Cystic Tumour of the External Auditory Meatus." *Archiv. de Physiol.*, No. 9, 1872.

DISEASES AND INJURIES OF THE FACE, NOSE, PALATE, &c.

ANNANDALE, THOMAS.—"Case of Rare Tumour of the Lower Jaw successfully removed without Division of the Bone." *Edin. Med. Journ.*, Jan., 1873. The tumour was a well-marked example of those rare tooth growths termed "Odontomes" by M. Broca. It was forcibly extracted with a pair of strong molar tooth forceps, the patient being placed under chloroform.

FERREOL.—"Tubercular Ulceration of the Tongue." *France. Med.*, Dec. 7, 13, 21, and 28, 1872.

WIMMER, E.—"The Operation for Nasal Polypi." *Archiv. der Heilkunde*, Nov., 1872.

INJURIES OF THE ABDOMEN.

BLEASE, T. T.—"Lacerated Wound of the Abdomen—Protrusion of Intestine and Omentum—Recovery." *Lancet*, Jan. 18.

HERNIA.

RICHARDSON, B. WILLS.—"Direct Scrotal Hernia having Primary, Secondary, and Tertiary Sacs—Several Inches of the Protruded Bowel suspended in the Sac-proper by Radiating Bands—Prolongation of one Long Band that descended from the Abdomen through the Ring—Both Testicles at the upper and anterior part of the Tumour." *Dub. Med. Journ.*, Jan. This is indeed, to use Dr. Richardson's expression, "one of the most curious, instructive, and valuable specimens of hernia on record."

DISEASES AND INJURIES OF THE RECTUM.

HANDYSIDE, P. D.—"Case of Abnormal Termination of the Rectum." *Med. Chir. Soc. Edin.*, July 3, 1872.

DISEASES AND INJURIES OF THE URINARY ORGANS.

CAZENAVE, J. J.—"Practical Study on the Treatment of Complete Retention of Urine caused either by Fibrous and Insurmountable Contractions of the Urethra or by Affections of the Prostate." *Bordeaux Med.*, Dec. 22 and 29, 1872.

MACNAMARA, RAWDON.—"On the Vermicular Action of the Urethra." *Surg. Soc. Irel.*, Jan 3. Dr. Macnamara believes that the vermicular action of the urethra on a catheter is such as to move the latter towards the bladder, a circumstance of practical significance in the treatment of stricture.

RICHARDSON, B. WILLS.—"Entero-Vesical Fistula with Disease of the Descending Colon, Sigmoid Flexure, and upper part of Rectum." *Dub. Med. Journ.*, Jan. Air having been expelled *per urethram*, Dr. Richardson examined the urine microscopically and found it to contain easily recognised constituents of fæces such as muscular fibre, hyaline tubes, starch grains, and mucous corpuscles, &c. Dr. Richardson, in the same journal, has an interesting paper "On Colles's Operation for Relief of Stricture at the Orifice of the Urethra."

DISEASES AND INJURIES OF THE GENITAL ORGANS.

HIRD.—"Case of Priapism lasting Six Weeks—Recovery." Charing Cross Hospital. Reported *Lancet*, Jan. 18.

DISEASES AND INJURIES OF THE BREAST.

LE DENTU.—"Hydatic Cyst of the Breast." *Gazette Med.*, Jan. 11.

AFFECTIONS OF THE EXTREMITES.

HEUTER, C.—"Resection of the Elbow-Joint by means of a Straight Incision on the Radial Side." *Deutsche Zeitschrift für Chir.*, Band. 2, Heft. 1, 1872. See Dr. McCormac's report in *Med. Record*, Jan. 15.

MARDUEL, P.—Treatment of Elephantiasis by Ligature of the Principal Artery of the Limb." *Lyon Med.*, Dec. 22, 1872.

MUNRO, W.—"Case of Elephantiasis of the Leg—Successful Amputation through the Elephantiasis Tissue." *Edin. Med. Journ.*, Jan. A great point of interest in this case was the diminution in the circumference of the thigh, which Dr. Munro attributes to the drainage from the wound. He suggests as a mode of cure, making longitudinal incisions so as to take out wedge-shaped pieces with the skin as a base from the elephantiasis tissue, then stitching the edges together, but leaving in drainage tubes so as to promote discharge from the deep part of the wound.

PONCET, M. A.—"Deformities produced by Arrest of Growth of one of the Bones of the Forearm, and the Causes of this Arrest of Development." *Lyon Med.*, Dec. 22, 1872.

WHARTON, J. H.—"Intracapsular Fracture of the Neck of the Femur." *Path. Soc. Dub.*, Jan. 11.

MIDWIFERY.

CAUSSE, SEVERIN.—"Cæsarean Section practised with success to both Mother and Child." *Bull. Gen. de Ther.*, Dec. 11, 1872.

KLOB.—"Cæsarian Section on account of Pelvic Tumour preventing Parturition." *Berl. Klin. Wochen.*, No. 52, 1872.

FOURRIER.—"Rupture of Uterus with Escape of Fœtus into the Peritoneal Cavity—Gastrotomy on the Fifth Day—Successful Result." *Bull. Gen. de Ther.*, August 15, 1872, and *Practitioner*, Jan.

DISEASES OF WOMEN.

O'FLYNN, D. O.—"Uterine Rheumatism." *Irish Hosp. Gazette*, Jan. 15.

PLAYFAIR, W. S.—"Lectures on Intra-Uterine Medication in the Treatment of Chronic Uterine Catarrh." *Lancet*, Jan. 4, *et seq.*

FRIEDKANDER, C.—"Dermoid Cyst of the Ovary." *Virchow's Archiv.*, Vol. 56, Part 3, 1872.

PEASLEE, RANDOLPH.—"Ovarian Tumours: Their Pathology, Diagnosis, and Treatment, especially by Ovariotomy." New York, 1872.

NOEGGERATH, EMIL.—"Latent Gonorrhœa in the Female Sex." Bonn, 1872. Without endorsing the author's views we may briefly recapitulate his most important statements. He asserts that gonorrhœa in man and woman, as a rule, lasts for life, and that cure is only apparent; gonorrhœa may be latent; wives of men who any period have had gonorrhœa are as a rule sterile; the secretion of patients suffering from latent gonorrh a fungus may be produced analogous to that formed in t fresh gonorrhœal secretion of men; eight out of every t men have had gonorrhœa. He says that the treatment sterility by injecting the semen into the proper uterin cavity is established in New York. The work is review in the *Edin. Med. Journ.*, Jan.

DISEASES OF CHILDREN.

ROGER, HENRI.—"Clinical Researches on the Disea of Infancy." Paris, 1872.

HENNIG, C.—"Two Special Forms of Hereditary Syph lis." *Jahrbüch. der Kinderheilkunde*, Dec., 1872.

LOREY, C.—"Cheesy Degeneration of the Bronchial Mesenteric Glands in Children and its relation to Hered tary Tuberculosis." *Jahrbüch. der Kinderheilkunde*, Dec., 1872.

Monti, A.—"Treatment of Whooping-Cough by Inhalation of Gazeol." *Jahrbüch. der Kinderheilkunde*, Dec., 1872.

Sonsino, Prospero.—"Infant Digestion of Starch." *Practitioner*, Jan.

Divet.—"Sudden Cessation of the Approach of Eclampsy after a Hypodermic Injection of Atropine and Morphine." *Ab. Med.*, Nov. 28, 1872.

Imlach, F.—"Dissection of a Malformed Fœtus with Deficient Anterior Abdominal Wall." *Med. Chir. Soc. Edin.*, July 3, 1872.

M'Laren, Dr.—At the *Obstet. Soc. Edin.*, Nov. 13, 1872, Dr. M'Laren brought forward a specimen in which there was but one lower extremity; the two feet were united by their outer edges, the great toes being to the outside. The penis seemed to spring from the coccyx.

THERAPEUTICS.

Ackermann.—"Action of Digitation on the Circulation and Temperature." *Deutsches Archiv. für Klin. Med.*, Vol. 9, and Dr. Brunton's paper in the *Med. Record*, Jan. 15.

Blatin, A.—"Nicotine as a Counter-Poison to Strychnine." *Union Med.*, Dec. 28, 1872. The author concludes negatively.

Decaisne, M. E.—"On the Use and Mode of Action of Cod-Liver Oil." *Acad. des Sci.*, Dec. 16, 1872.

Gellhorn.—"Cutaneous Eruption following the Use of Chloral Hydrate." *Allgemain Zeitschrift für Psych.*, Vol. 19, Part 4, 1872.

Heidenheim.—"On the Influence of Belladonna on Secretion." Heidenheim's experiments, *Pflüger's Archiv.*, Vol. 40, go to prove that arrest of secretion of the sub-maxillary gland is due to paralysis of the true secretory fibres in the Chorda Tympani, not of the vaso-inhibitory fibres. His experiments taken in conjunction with Dr. Sydney Ringer's researches (*Practitioner*, Aug. and Oct., 1872, and "Handbook of Therapeutics," 2nd edition), would appear to indicate that arrest of secretion of the sudoriferous and mammary glands by the local application of belladonna is due to paralysis of ends of special secreting nerves. See Dr. Brunton's paper, *Med. Record*, Jan. 15.

Little, James.—"On the Use of Digitalis in the Failing Heart and Delirium of Acute Diseases." *Med. Soc. Coll. Phys. Irel.*, Jan. 8. It is impossible to do justice to this valuable paper in abstract; it merits the attentive consideration of physicians.

Poore, G. V.—"On the Influence of the Continuous Galvanic Current over Voluntary Muscular Action." *Practitioner*, Jan. Dr. Poore believes that by the passage of a continuous current through muscles, or the nerves to them, their susceptibility to the stimulus of the will is increased, and their voluntary power thereby enhanced. His experiments tend to prove that force, as well as the endurance of voluntary muscular action, is increased by a galvanic current.

Ringer, Sydney.—In the *Med. Record*, Jan. 15, Dr. Ringer gives a very full analysis of recent researches on the physiological and therapeutical action of the bromides of potassium and ammonium, referring more particularly to the work of Drs. Clarke and Armory.—"An Abstract of the Physiological and Therapeutical Action of the Bromide of Potassium and Bromide of Ammonium." Boston, 1872.

MEDICAL JURISPRUDENCE.

Graham, Thomas.—"Case of Hypospadias with Cleft Scrotum—Believed a Female until Fourteen Years of Age." There was no evidence that any of the female organs were present; the peculiarities of development consisted of deficiences in the male structures. *Edin. Med. Journ.*, Jan. In No. 123 of the *Edin. Med. and Surg. Journ.*, Dr. Handyside published a parallel case.

HYGIENE.

Buchanan.—"On the Concurrence of Epidemics. *Epidem. Soc.*, Jan. 8.

Furstenburg, M.—"Cairo and its Climate." *Lancet*, Jan. 11.

Roque.—"Hereditary Degeneration produced by Slow Lead Poisoning." *Mouv. Med*, Dec. 28; quoted *Lancet*, Jan. 11.

N.B.—Several important papers are reserved for notice in our next Retrospect.—Ed. Retrospect.

STUDENTS' COLUMN.

LECTURES ON HUMAN ANATOMY.

By Walter Rivington, M.S., Lond., F.R.C.S., Eng.,

Surgeon to the London Hospital and Lecturer on Anatomy at the London Hospital Medical College.

Lecture II *(continued)*.

In the various text-books which you consult you must be prepared to find conflicting statements. Some of these discrepancies I may have occasion to point out as we proceed. Here I would call attention to some which regard the Vertebræ. The bodies of the Cervical Vertebræ are described by Ward, Harrison in the *Dublin Dissector*, and Ledwich, as thicker in front than behind; by Gray, as of equal depth anteriorly and posteriorly; by Humphry, as having their upper and lower surfaces "parallel, or even actually farther apart behind than in front." Quain and Holden say nothing on the subject. So far as my measurements have extended, they agree with the latter part of the conclusion of Professor Humphry. Of the Vertebræ now before us, I find that the third Cervical is 5-8ths of an inch in depth both in front and behind; the fourth is 5-8ths of an inch behind and not quite 5-8ths in front; the fifth, sixth, and seventh measure half an inch in front and 5-8ths of an inch behind. These measurements were made on the outside of the Vertebræ, but the fairest method of measurement would be to measure vertical sections.

The bodies of the Lumbar Vertebræ are described by Ward, Harrison, Ledwich, and Humphry, as thicker before than behind; Gray, I believe with more justice, states that, with the exception of the fifth, the Lumbar Vertebræ are about equal in depth in front and behind. In the vertical section of the first three Lumbar Vertebræ before me I can detect no difference in depth. Measuring other bones on the outer surfaces I found a preponderance in favour of the posterior surfaces.

The fact that the Cervical and Lumbar Vertebræ form curves with the convexities forwards has doubtless tended to create a prejudice in favour of the anterior surfaces, and the prolongation downwards of the lower edge of the anterior surfaces of the Cervical Vertebræ gives a deceptive appearance of length to the front of the body. The posterior surfaces of the Dorsal Vertebræ are stated by Humphry to be flat; by Ward to be "concave transversely;" by Gray to be deeply concave behind;" by Harrison to be "very concave behind." As there can be no doubt about the transverse hollowing, it is presumable that Professor Humphry refers to a flatness of the posterior surface in the vertical direction. But the most curious discrepancy which I have met with is in the descriptions of the bodies of the Dorsal Vertebræ. Gray describes the body as "heart-shaped, and broader in the antero-posterior than in the lateral direction;" Ward, as "somewhat triangular in form, most extended in the antero-posterior dimension;" Harrison, as "in most longer from before backwards than transversely." Following these authorities, and deceived by the aspect of the Vertebræ, I have hitherto stated in lecture that the antero-posterior diameter is the longer. The actual measurement of two sets of Dorsal Vertebræ has led me to revise my opinion. The following are the measurements of the upper and lower surfaces of one of the sets in question, made antero-posteriorly in the middle of the Vertebræ and transversely in front of the facets for the ribs :—

MEASUREMENT OF DORSAL VERTEBRÆ.

		Antero-Posteriorly.	Transversely.
Dorsal.		Inches.	Inches.
1st.	above.	$\frac{5}{8}$	$\frac{7}{8}$
	below.	$\frac{6}{8}$ nearly	$1\frac{1}{8}$
2nd.	above.	$\frac{6}{8}$ nearly	$1\frac{1}{8}$
	below.	$\frac{6\frac{1}{2}}{8}$	$1\frac{2}{8}$
3rd.	above.	$\frac{7}{8}$ nearly	1
	below.	$\frac{7}{8}$	$1\frac{2}{8}$
4th.	above.	$\frac{7}{8}$	1
	below.	1	$1\frac{2}{8}$
5th.	above.	1	$1\frac{1}{8}$
	below.	1	$1\frac{3}{8}$
6th.	above.	1	$1\frac{3}{8}$
	below.	$1\frac{1}{8}$	$1\frac{3}{8}$
7th.	above.	$1\frac{2}{8}$	a little over $1\frac{2}{8}$
	below.	$1\frac{2}{8}$	$1\frac{3}{8}$
8th.	above.	$1\frac{2}{8}$	$1\frac{1}{2}$
	below.	$1\frac{2}{8}$	$1\frac{5}{8}$
9th.	above.	$1\frac{2}{8}$	$1\frac{1}{2}$
	below.	$1\frac{3}{8}$	$1\frac{5}{8}$
10th.	above.	$1\frac{2}{8}$	$1\frac{5}{8}$
	below.	$1\frac{3}{8}$	$1\frac{4}{8}$
11th.	above.	$1\frac{3}{8}$	$1\frac{4}{8}$
	below.	$1\frac{3}{8}$	$1\frac{6}{8}$
12th.	above.	$1\frac{3}{8}$	$1\frac{6}{8}$
	below.	$1\frac{3}{8}$	$1\frac{6}{8}$

The second set yielded similar measurements, but two or three of the Central Vertebræ of the series showed a near approach to an equality. In no single instance was the longest antero-posterior diameter greater than the longest transverse (*a*). The fifth edition of Quain stated the matter more correctly in saying that—"The breadth of the body from side to side exceeds the depth from before backwards much less than in the cervical or lumbar vertebræ." The seventh edition says that the "antero-posterior and transverse diameters are nearly equal." Plates are sometimes right when descriptions are wrong. If anyone will take the trouble to measure the plate given in Quain of a sixth dorsal vertebra, he will find the transverse diameter considerably in excess of the antero-posterior. This is also the case with the representations in Humphry of sections of the fourth dorsal vertebra, and with the plate in Flower's "Osteology." In the vertical measurements in front and behind I have found an average superiority of the posterior to the extent of 1-8th of an inch.

I must now refer more particularly to some *Tubercles* which are found in connexion with the Transverse Processes of the Dorsal Vertebræ and the Articular Processes of the Lumbar Vertebræ. If you will examine the vertebral column of this Eagle's or this Vulture's Skeleton, you will see that the dorsal transverse processes bear at their extremities elongated tubercles which, projecting upwards and downwards, meet those of the vertebræ above and below, and, interlocking, contribute materially to give solidity and steadiness to the Spine. The Thorax is thus enabled to afford a firmer attachment to the strong muscles which move the Wings. These tubercles, although rudimentary in man, are often plainly visible. They are best seen in the central dorsal vertebræ on the hinder aspect of the tip of the transverse process, and are called by Professor Humphry (*b*) "the *superior* and *inferior tubercles* of the transverse processes." A third tubercle is placed in front and, bearing the facet for the rib, is named the *costal tubercle*. If you will now look at this skeleton of an Ape, you will see projecting downwards *from the point of junction of the tranverse and articular processes*, what are in reality the inferior tubercles of the dorsal transverse processes, altered in position and so developed as to overlap the upper articular processes of the vertebræ below. These inferior tubercles (or *anapophyses*) are also well developed in the Carnivorous Mammals, especially the feline tribe.

Similarly in Man, the *superior tubercles* (or *metapophyses*) of the dorsal transverse processes become transposed in the lumbar region, and, forming a connection with the superior articular processes, are sometimes called the *mammillary* processes.

The *inferior tubercles* (or *anapophyses*) are transferred to the point of junction of the transverse and superior articular processes, and are called *accessory* processes.

The *third* or *costal tubercle* of the dorsal transverse process is represented by the long lumbar transverse process.

In most Vertebrate Animals below the higher or anthropoid Apes, notably in Carnivora, the spines of the anterior thoracic vertebræ lean backwards, while those of the posterior thoracic and lumbar vertebræ lean forwards, converging either to a point between two vertebræ, called the "*centre of motion*," or to a thoracic vertebra with an upright spine termed the *anticlinal vertebra*. Here the thoracic vertebræ assume lumbar characters, and the elongated tubercular transverse processes break up as it were into the *Metapophyses*, *Anapophyses*, and *Lumbar Transverse Processes*, all of which are conspicuous in these animals (*a*).

In the Dolphins and other Cetaceous Mammals you may trace the transference of the superior tubercles of the transverse process (*metapophyses*) in the back to the sides of the spinous process from which they project, so as to embrace the spinous processes of the preceding vertebra. In the Hare you will find long *metapophyses* and short *anapophyses*. In the Edentated Mammals, *e.g.*, the Sloths, Megatherium and other American representatives, the *anapophyses* are remarkably developed, until in some, such as the great Anteater, the vertebræ are interlocked by several joints accessory to the ordinary articular processes (*zygapophyses*). In the Armadillos the bony armour or carapace is upheld by the long *metapophyses*. Lastly, in this skeleton of a Kangaroo, one of the Marsupial Mammals, you will find the lumbar vertebræ presenting both *metapophyses* and *anapophyses* in a greatly developed shape.

The Cervical Vertebræ of Mammals are all but universally seven in number. The exceptions seem to be three :—In the Manatis there are six, in all the known species of three-toed Sloths (Bradypus) there are nine, and in a species of two-toed Sloths (Cholœpus Hoffmannii) there are six. In the elongated neck of the Giraffe and in the stunted necks of the Whale, Elephant, and Rhinoceros there are but seven. Attached to the bodies of the Cervical Vertebræ in the Horse and other animals there are projecting processes called *Hypapophyses*; on the bodies of the human Cervical Vertebræ you may sometimes find, on each side of the median line, representative tubercles which give attachment to the Longus Colli. In Birds and Reptiles these tubercles among others are well developed and sometimes enclose a foramen for the transmission of the Carotid Arteries.

Among Mammals the Thoracic and Lumbar Vertebræ bear a relation to each other, their aggregate number "being tolerably constant in any given group of animals, and any increase of the one being at the expense of the other. Thus, in all known Artiodactyle Ungulata there are nineteen thoracico-lumbar vertebræ, but these may consist of twelve thoracic and seven lumbar, or thirteen thoracic and six lumbar, or fourteen thoracic and five lumbar.

The smallest number of thoracic-lumbar vertebræ in Mammals occurs in some Armadillos, which have but fourteen. The number found in Man, the higher Apes, and most Bats, viz., seventeen is exceptionally low ; nineteen prevails in the Artiodactyles and very many Rodents. ; twenty or twenty-one in Carnivora and most Insectivora, twenty-three in Perisso-dactyla. The highest and quite exceptional numbers are in the two-toed Sloth (Cholœpus) twenty-seven, and Hyrax thirty.

The prevailing number of rib-bearing vertebræ is twelve or thirteen, any variation being generally in excess of these numbers" (Flower, *op. cit.*, p. 24). Setting monsters altogether aside, it is very rare to find in man any increase or decrease in the number of vertebræ. Otto states that "in very rare cases of otherwise well-formed persons we miss one of the Cervical Vertebræ. Very much more rare is the actual increased number of the pieces of the Spine ; it is but trifling, however, as we never notice more than one superfluous vertebra. Thus, we observe in very rare instances eight cervical vertebræ ; more commonly thirteen dorsal, and six lumbar vertebræ in man." (*b*) He refers to a skeleton with thirteen dorsal vertebræ in the Anatomical Museum at Kiel.

(*a*) Of course a larger number of observations is necessary to determine the average measurements.

(*b*) "The Human Skeleton," p. 141.

(*a*) Flower : "Osteology of the Mammalia," p. 47.

(*b*) South's translation of Otto's "Compendium," p. 96.

The number of rib-bearing vertebræ may be increased and the relative number of vertebræ in two of the regions of the spine may be altered. Thirteen dorsal vertebræ may be found with only four lumbar. My distinguished predecessor in this chair, Mr. John Adams, who, as a lecturer, much resembled Abernethy, has informed me that in one subject he found six cervical vertebræ associated with six lumbar.

A want of symmetry may be observed in many vertebræ. Sometimes they present inequalities of depth on the two sides, compensated for by inequalities of the opposite kind in neighbouring vertebræ. Sometimes they appear to be twisted to one side, especially in the dorsal region. Many persons perfectly sound present a slight degree of lateral curvature of the spine. Sometimes, without any actual twist, the two lateral halves are unequal in size, as may be determined by antero-posterior section or ocular inspection.

Bony outgrowths are not uncommon, especially in the form of plates projecting from the margins of the vertebræ and round the facets for the ribs.. You may observe these plates in some of the specimens before you. Spicula of bone may be found growing within the canal from the margins of the inferior articular processes. Professor Humphry relates a case in which a bony outgrowth from the hinder part of one of the dorsal vertebræ increased in size and pressed on the spinal cord, inducing paralysis, which lasted for many years before death, and he refers to a case recorded by Dr. Reid, in which a conical exostosis from the posterior part of the Odontoid Process of the axis caused fatal compression of the cord. Our collection contains a specimen, presented by Mr. Curling, of a portion of the Vertebral Column from a case of Tetanus. On the posterior surface of the bodies of the dorsal vertebræ, a flattened ovoidal tumour projects into the canal. It appears to have compressed the spinal cord, which was softened and vascular at the spot. In a case related by Dr. Ogle, a collection of matter, in connection with a carious vertebra, and disintegrated intervertebral substance pressed on the cord and caused paralysis of the lower limbs (*a*).

Contrast with such morbid products and growths as these, the conservative deposit of bone which takes place in certain curvatures of the spine, or as the result of strains. Our Museum contains some interesting specimens of this nature. The first is an anchylosis of five of the dorsal vertebræ in a horse by a thick deposit, apparently bony, covering the outer surface of the bodies. The second (marked G. bb. 18) is an anchylosis of the lower seven dorsal vertebræ of a man who died after fracture of the spine. The ninth, tenth, eleventh, and twelfth are firmly welded together by a deposit of new bone external to them and continuous across the intervertebral substance. The deposit has been broken across opposite the intervals between the sixth and seventh, seventh and eighth, and eighth and ninth vertebræ. The body of the ninth is fractured vertically. The patient was a middle-aged man, and walked into the hospital. During life there were no symptoms of injury to the spinal cord and no displacement, indeed, the fracture of the spine was a *post-mortem* discovery. In both of these specimens there is a long belt of bone in front of the bodies, and on one side only. In neither are the intervertebral substances involved (*b*). In both the deposit would appear to be of the same character and similar to the irregular bony growths by which the vertebræ of horses and asses whose backs are subjected to strains may be soldered together (*c*).

The third is a dried specimen of the human Cervical Vertebræ from the Axis to the Seventh Cervical. The bodies of all these six Vertebræ are firmly united together. The bony matter has invaded and obliterated the inter-Vertebral disks, and the Vertebræ form a curve with the *concavity* forwards. This specimen is marked F b. 35, and has no further history or description than Ankylosis of all the Cervical Vertebræ except the first.

The skeleton of the donkey in our musuem, has two of the Spinous Processes near the centre of motion firmly anchylosed. Like the London cab horses, and the sea-side asses, he was probably an ill-used animal, whose patient work was repaid with blows. Not like Sancho Panza's celebrated ass Dapple was he, nor like the ass over whom Sterne, in his "Sentimental Journey," found his master weeping.

"Thou hast one comfort friend, said I, at least in the loss of thy poor beast: I am sure thou hast been a merciful master to him. Alas! said the mourner, I thought so when he was alive, but now that he is dead, I think otherwise. I fear the weight of myself, and my afflictions together, have been too much for him—they have shortened the poor creature's days, and I fear I have them to answer for. Shame on the world! said I to myself. Did we but love each other as this poor soul loved his ass—t'would be something."

WEDNESDAY, FEBRUARY 12, 1873.

THE IRISH UNIVERSITY BILL IN ITS BEARING ON MEDICAL EDUCATION.

THE Irish University question is, it would appear, to be the nine days' wonder of the Parliamentary year, and we wait only from day to day for an elucidation by Mr. Gladstone of the salient characteristics of the coming measure. Already we have had, from vacation utterances and from the hints which have fallen from Cabinet hangers on, some foreshadowing of the objects and machinery of the measure. Several weeks since we stated our impression, founded on the authority of private information on which we had reliance, that the Irish University Bill would not only deal with the question of Medical education and qualification in Irish Universities, but would, almost of necessity, go some distance towards a wide settlement of the future Medico-educational system of Ireland. On the 25th of December we stated that we had been assured that the question of Irish University Education and the reconstruction of Trinity College, would deal with the granting of Medical Degrees in Ireland in a very wide and reforming spirit. As it will be a matter of great difficulty to draw a line of religious neutrality in the curriculum of the Faculty of Arts, and impossible to touch the Divinity School, and inasmuch as the Faculties of Law and Engineering are comparatively insignificant branches of University education, it

---

(a) "Pathological Society's Transactions," 1868. A Plate is given with the case.

(b) See "London Hospital Reports," Vol. III., p. 355.

(c) See South's Otto, p. 197.

is stated to us that the Faculty of Medicine will be a principal object of the contemplated reform. We are assured that the Government desires, if possible, to make a comprehensive Medical qualification part of their scheme, and are considering whether the arrangement for conjoint examination, which has been so long in course of settlement, cannot be made part of their plan.

We are aware that minute enquiries have been instituted at the instance of the Ministry within the last few months into the entire subject of Irish Medical education, and that members of the Medical profession, whose advice would probably be accepted with confidence by the present Government, have been privately consulted on the part of the Ministry.

Both the information which we possess, and previous experience of Mr. Gladstone's legislation, lead us to expect something very decisive in the way of Irish Medico-examination reform when the details of his University Bill come to be unfolded. It would be in accordance with precedent that the unification of Licensing Bodies in a Conjoint-Examination Scheme should be tried in Ireland, just as Church Disestablishment and tenant right law have been before the larger and (to Ministers and English M.P.'s) more important interests of the Profession in England be submitted to the hazard of a radical reform. From all these considerations we shall feel no surprise if we find that Mr. Gladstone's University Bill plunges into the thick of the Medical controversies which have given the law-givers of the Profession in Ireland so much to think of within the last two or three years, and, if our anticipation proves correct, we shall look forward to a season of stormy debate on these subjects.

It is not without very grave apprehension that we await the elucidation of the matter. We entertain the profoundest distrust of a Medico-educational reform of the slashing Gladstonian type, debated not as a separate piece of important legislation, but as an apparently insignificant item in the detail of a great party and political question.

If the future of Irish Medical education be made a part of the great question of Irish education, we may be sure that whatever scheme Mr. Gladstone may hit upon—be it good or bad—will not be materially affected by any opinion the Profession may entertain or any opposition they may be able to offer.

Apart from this apprehension, we should be well satisfied to see the question of Irish Medical education extricated by a shake of Mr. Gladstone's powerful hand from the tangle in which it is now involved, and we see no reason why reforms in Medical education and qualification should not be initiated in a division of the Kingdom which has shown itself most ready for the change.

THE LATE DEATH DURING THE USE OF NITROUS OXIDE.

All those interested in the questions that lie around the subject of anæsthetics—and which of our readers is not—will probably heartily endorse all we said last week respecting the need of a *post-mortem* investigation into the exact cause of the recent death at Exeter. This, however, having been refused, it is gratifying to find that such information as could be obtained has been collected in such form as to make it reliable. Mr. Braine, who has carefully studied the subject of anæsthesia, has been to Exeter for the express purpose of investigating on the spot the late painful occurrence. Mr. Browne-Mason, the operator, Dr. Pattinson, the brother-in-law, and usual Medical attendant of the patient, who was present at the operation, and Dr. Drake, who was fetched on the signs of danger being manifested, and took part in the attempts to restore animation, have given every information in their possession to Mr. Braine. They have, moreover, reduced the history of the case to writing, and handed it over to Mr. Braine, who has already presented it to the Odontological Society of Great Britain, where it has been discussed with no little interest.

The paper in question was read in the first person singular, in the name of Mr. Browne-Mason; but, as we understood that it had been prepared with the co-operation of Drs. Pattinson and Drake, and is endorsed by these gentlemen, we look upon it as possessing the importance of a joint production.

Passing over the dental details, we find that the lady was 38 years of age, in good health, rather stout, and considered free from thoracic disease. We are told, however, that she had an elongated uvula and enlarged tonsils, and in consequence of these conditions her breathing, when hurried by exertion, was "snorting." The gas was evidently quite pure, the dress was loosened at the throat, and the usual face-piece was employed. An ordinary wooden gag was used.

The other details of the accident are thus stated in the paper presented to the Odontological Society:—

"I gave Dr. Pattinson charge of the pulse at the left wrist. After the patient had taken about half a dozen respirations, he exclaimed that the pulse was not so rapid; but he states that its volume did not vary. I removed the face-piece, saying 'Let us do without it,' and cut off the crown of the tooth with the excising forceps. This did not hurt the patient, as the pulp was gone, but on my thrusting a spear-pointed instrument into the pulp-cavity, and with a twist splitting the fangs, so much pain was produced owing to the previous inflammation of the periosteum of the fangs, that the patient declared that she could not bear any further operation unless more gas were given her. On rinsing out her mouth, the water was returned tinged with blood. An interval of ten minutes took place, during which the patient was somewhat hysterical, and, the bleeding having quite ceased, the same gag was replaced in its former position and the inhalation resumed. Dr. Pattinson cannot agree that the bleeding had *quite* ceased; it was never other than slight, but he thinks there must have been a minute quantity of blood exuding from the gum during the second inhalation. At Dr. Pattinson's request, I now took charge of the pulse at the right side, while he held that at the left. The patient took the gas well, but just before losing consciousness she raised her right hand and pushed off the inhaler, which I replaced, and continued the inhalation. Dr. Pattinson states it as his impression that no more gas was given after the inhaler was pushed away, the eyes never having closed. I noticed that the pupil of the right eye was slightly dilated, and on touching the conjunctiva, reflex action took place, showing that this membrane was not completely insensible. On removing the inhaler, I am quite certain, no blueness existed; and, finding the stumps exposed and uncovered with blood, I proceeded to operate, and attempted to seize the palatine fang with a pair of stump-forceps, but, the edge giving way, I dislodged it with an elevator, with which I afterwards easily removed the outer fangs. The whole operation lasted about three-quarters of a minute. I received all the fragments of tooth in my fingers, and feel quite sure nothing passed backwards into the throat. I then saw, for the first time, blueness of the lips; but Dr. Pattinson had noticed that, during the operation the ear on the right side was bluish, and on looking at the face saw blueness there also, but he says he did not mention it, as he had heard of this discolouration occurring at gas administrations. The symptoms now became alarming, the features

> appeared puffy and swollen, the eye-balls protruding, the breathing thick and stertorous, the point of the tongue thrust between the teeth, but no convulsive movements were visible. The pulse and the appearance of the pupils at this period were not observed, attention being paid to more urgent matters. An old attendant who was in the room exclaimed—'Take out he gag; she is choking.' This was the first suspicion Dr. Pattinson had anything was going wrong. The gag was then forcibly removed. It needed great force to separate the jaws, and possibly it was then chipped as you now see. It was erfect when inserted, and exactly where I placed it at first.
>
> "Mr. Braine, on examining the gag ten days after the operation, pointed out to me the broken surface which I had not seen before, but, as I had never looked at it since, the piece may have been broken accidentally after its use on this occasion. I then thrust the head forward, to see that no blood got into the throat, and passed my finger down over the tongue to draw it forward, as it had now dropped back. From his time, Dr. Pattinson thinks there was fixity of expression, and no further entrance of air into the chest. The window was thrown open, and the face dashed with cold water. I now left to fetch further assistance. Whilst I was absent, Dr. Pattinson continued his endeavours, and applied strong ammonia to the nostrils; there appeared to him to be some sensibility, inasmuch as she seemed to recoil slightly from the pungency of the ammonia. He then noticed about a table-spoonful of water lying at the back of the mouth, which had lodged there during the time he was dashing it over the face; he drew the head forwards to allow it to run out. I then returned, after an absence of about three minutes, with Dr. Drake, for years past one of the most eminent physicians of the city, and at the present time Consulting Physician to the Devon and Exeter Hospital. At this time, the pulse was felt in both radials, and in the left carotid. I substituted the handle of the forceps exhibited for my finger, to keep the tongue forward, for the purpose of allowing more free access of air; and Dr. Drake performed artificial respiration by alternately pressing on the throat and then allowing it to expand by its own elasticity, at the same time raising the arms; and this was continued until the pulse ceased to beat. When Dr. Drake came into the room, he found the patient in the position described; her countenance was dusky, face swollen, eyes projecting; the tongue was in the mouth, with mouth open. He put his finger into the throat, to find that nothing interfered with access of air, as far as he could; she made three or four expiratory movements, accompanied by a slight sound. During this time, the pulse beat regularly, and continued to do so nearly two minutes after all respiratory movements had ceased. It was quite impossible for him, seeing her in a dying state a few moments only before death, to form any positive and precise inference as to the immediate cause of death, but his impression is as stated at the inquest.
>
> "The blueness about this time began to disappear; all our efforts were unavailing; the pulse ceased to beat, and death ensued. Two hours and a quarter after death, the blueness had entirely disappeared. It is much to be regretted that a *post-mortem* examination was not permitted, as it would doubtless have cleared up many points which must now ever remain in obscurity."

Several suggestions were made at the Society to account for the death, and others have not been wanting. Indeed, the sad occurrence has called forth correspondence, not only in the Medical but in the lay press. This is certainly to be regretted. Especially is it unfortunate that in a case like this, in which no autopsy was permitted, that so many suggestions should be made in the daily papers to the bewilderment of the public, and to the confirmation of the prejudice that doctors never do agree.

When we compare the various explanations offered, we feel inclined to look upon them all as futile attempts to explain away an occurrence for which we have from the first been prepared. The public will not care one jot whether the patient died from one or another of the accidents that are incidental to anæsthesia; but they cannot help feeling anxiety now that they learn that a person may die while "asleep from the gas"—a fact that has in some quarters been too recklessly denied.

MR. HARGRAVE AND THE COUNCIL OF THE IRISH COLLEGE OF SURGEONS.

We understand that in spite of the legal opinion against the legality of his election, and the vote of want of confidence in him adopted unanimously by the Council, Mr. Hargrave still continues to assume the position of representative of the College, and we believe, that at its meeting on Thursday last, the Council confirmed its previous vote, and adopted a resolution of regret, that Mr. Hargrave had not resigned. A notice of motion was handed in to the effect, that the Council being advised that the late representative was not validly elected would proceed at once to the choice of a fit and proper person to fill the office. This motion will come on for debate on Thursday next, and we have reason to hope, will be adopted. Its acceptance is really a matter very much of necessity. The Council has been distinctly informed by its legal adviser, that Mr. Hargrave's election was "irregular and informal, and that the course pursued was highly objectionable and such as ought not to have been allowed." That the election "could and ought to have been set aside, and that considering the fact that Mr Hargrave and most of the gentlemen now on the Council were parties to a transaction quite contrary to their ordinances, and in violation of their rules, and illegal, it would be but becoming on the part of the Council and Mr. Hargrave to proceed at once to a new election."

With such an opinion before them, the Council could not possibly take so grave a responsibility as that of sending forth a delegate, whom, disregarding for a moment the question as to his mental and physical competency, they knew to be illegally in occupation of his office. If they were to permit Mr. Hargrave to present himself at the Medical Council, under the authority of their silence he would, possibly, not be allowed to take his seat, and if he were, his first vote would be challenged as invalid, and all his proceedings set at nought by the members of the Medical Council. Moreover, the responsibility of every act and word of his would rest on those who knowingly permitted him to proceed as their delegate, without any legitimate authority to do so. We have to remind the Council, that on this day month the Medical Council holds its first meeting, and the time is short for the election, and instruction of their representative.

◆

Notes on Current Topics.

Septicæmia.

At the meeting of the *Académie de Médecine*, Jan. 21, some startling evidences as to the subtilty and danger of the septicæmic virus were produced. M. Davaine had introduced the subject to the Society at a previous meeting, and supported his observations by direct proofs of the action of the ferment. So startling were these that not only did M. Chassaignac characterise them as incredible, but M. Bouley, in renewing the discussion, stated, as we are informed by the correspondent of the *Medical Times and Gazette*,—"I must avow frankly that I, too, was at first seized with profound astonishment at the marvels displayed before us, and my first sentiment was one of doubt and incredulity, and it was in that sense I addressed the

Academy." In place of opposing mere sceptical assertions, however, M. Bouley requested M. Davaine to repeat the experiments in his presence, and from their results became convinced of the accuracy of his statements. Six watch glasses were placed on a table. Into the first, 100 drops of water were placed, and to these was added one drop of blood from a septicæmic rabbit; the whole was stirred so as to produce a solution of 1 in 100. One drop of this was placed in the second glass, containing 100 drops of water, and a dilution of 1 in 10,000 produced. In the third glass, a drop from the second gave a dilution of 1 in 1,000,000. In the fourth glass, a drop of the third dilution added to the 100 drops of water produced a dilution of 1 in 100,000,000. In the fifth glass, similarly treated, there was a dilution of 1 in 10,000,000,000; and in the sixth glass, a drop of the fifth dilution gave a trillionth (1 in 1,000,000,000,000). Matters being so disposed, four rabbits were inoculated respectively with the first, second, third, and fourth dilutions, a horse with the second, and a guinea-pig with the first. Next day all the rabbits were dead, the guinea-pig fell ill but recovered, and the horse sustained no harm. Since that time he has too frequently seen the efficacy of these minute dilutions to have any doubt of the fact whatever. Incomprehensible it may be, but of the fact there can be no doubt. M. Bouley communicated an account of numerous experiments which he has performed, showing that dogs also can be killed by the septicæmic virus derived from the rabbit, and that such virus derived from the horse possesses much less virulence than that furnished by the rabbit.

These announcements are certainly most remarkable, and would be well calculated to excite our scepticism were they not supported by facts. The occurrence of the syphilitic corpuscles lately described, as well as the apparent cholera germ, gives fresh impetus to histological research in this direction, and must eventually succeed in unfolding those hitherto unascertained sources of disease recognised as "occult causes."

Hospital Sunday Movement.

THIS laudable movement promises daily to be more successful, if we can judge by the statement that the Hospital Sunday collections at Nottingham on Sunday last realised about £850, and the working men's contributions on Saturday amounted to £150.

It seems strange that in Dublin such a movement should not be carried out. Efforts have been lately made to set in motion so laudable a method of applying to the charitable and benevolent, and it is to be hoped that, like some Irish undertakings, it will not fail from want of unanimity or anything of sectarian difficulty. If the Dublin clergy and public were in accord for once in such an object, a handsome sum could be realised for distribution. The practical hints thrown out by the reporter of the Nottingham movement should not be lost sight of, and the collected funds should be impartially distributed amongst "the legitimate charities" and working institutions. It is a hopeful sign to see that the "working men's" contributions amounted to so respectable a sum.

The Ether Anæsthetic Question.

WE find that one of the points so often mentioned as of importance in the successful administration of ether as an anæsthetic has been corroborated by the observation of the results in the Birmingham and Midland Eye Hospital. Mr. Smith, the house surgeon, observes that while, "during the last few months, ether has almost entirely taken the place of chloroform in the hospital," it has been found that, the nearer the approach to total exclusion of atmospheric air, the more satisfactory are the results obtained, and that when ether is administered by any method which allows a greater admixture of air, several inconveniences must be expected, viz., the necessity for using a larger quantity of ether, a longer period of administration, violent excitement on the part of the patient, great difficulty in inducing perfect anæsthesia, and the annoyance of an atmosphere loaded with the vapour, the odour of which clings to the administrator and others present for six or eight hours afterwards.

It is remarkable that this is the very caution which we have more than once chronicled in our pages as so insisted upon by Dr. Morgan, of Dublin. So far back as last autumn he noted this fact, and drew the particular attention of surgeons about to use ether as the safer, and we must think more satisfactory, agent, to the necessity of excluding air. The inhaler which he has devised, and which was shown at the Surgical Society of Ireland in the early part of this session, is intended for this very purpose, and is so constructed as to allow free in- and expiration of the ethereal vapour in the same chamber. We have frequently submitted cases in ophthalmic practice to etherisation by the use of the inhaler so constructed, and we can fully confirm its value and efficacy, altogether attributable to the special arrangement for securing the exclusion of atmospheric air, which, as noted in the Birmingham Eye Infirmary, secures the most satisfactory results. Indeed, the question seems to resolve itself almost into one of the exclusion or non-exclusion of air.

The question has received increased interest since the report of a case of death from nitrous oxide gas inhalation for the simple operation of removing a tooth; and as this anæsthetic has been said to be so free from danger, the importance of the warning so early given should not be underestimated. The remarks of a weekly contemporary are most apposite on this subject; when summing up the details of the case it states—"This lesson must not be forgotten. From no agent have there been so many hair-breadth escapes from death as from this gas; and probably of late some persons every day have been brought within the minutest line of the danger to which Miss Wyndham succumbed. Indeed, a leading dentist told us but a few weeks since that he never operated until the breathing had temporarily ceased. But because through all this risk there have been, it is assumed, no fatal accidents, the administration has gone on in contempt of warning and of obvious danger.

"The facts teach another lesson bearing on the cause of death. They show clearly that the assertion, so constantly made, that nitrous oxide gas does not affect the heart, is without foundation, for the first symptom presented by Miss Wyndham under the influence of the gas was rapidity of pulse, with diminution of volume."

The Ether Committee appointed by the Royal College of Surgeons and the Surgical Society of Ireland has arranged a satisfactory system of comparative investigation of the advantages of either of the anæsthetics, ether or chloroform, and has struck out a tabular system of queries which seem practical and complete. What with deaths from chloroform and with the lately recorded one from nitrous oxide which has hitherto been supposed to be free from danger, it is time that, without favour, fear, or prejudice, a conclusion should be arrived at.

Vaccino-Syphilis.

Fresh interest in this question has been aroused by another series of cases just now recorded by Mr. Hutchinson in London, who has brought the subject before the Royal Medical and Chirurgical Society in a form which cannot fail to seriously impress practitioners with responsibility in cases of vaccination, and call for the exercise of the greatest caution, not only in the selection of vaccinifers, but in the mode and extent of obtainingthe true lymph. The evidences of vaccination conveying the syphilitic poison have been too indubitable since the mishap known as the "Rivalta tragedy" first gave alarm. This remarkable tragedy is thus recorded:—On May 21, 1861, an Italian child, aged 11 months, was vaccinated from a tube; 46 other children were subsequently vaccinated from this child's vesicle, and from Manzona, 1 of these 46, 17 other children were vaccinated in ten days, of these 39 of the first and 7 of the last lot (being 46 out of 63) were attacked by syphilis. Twenty of the mothers or nurses of these 46 children contracted syphilis from them, and it was found that the child which was the original vaccinifer was undoubtedly infected. From the occurrence of this accident until now cases have from time to time been recorded, all of which, while confirming the communicability of syphilis by the process of vaccination, equally tend to prove that, provided the lymph only be taken and that the vaccine vesicle is not too fully drawn upon for a lymph supply, the danger of infection is *nil*. The cases just now related are remarkable, and we concur with the *Lancet* in the opinion that the inference from the group of cases related must be decidedly in favour of the *possibility* of communication of syphilis by the inoculation either of the blood of a syphilitic vaccinifer, or of the serum which oozes into the vesicle if the vaccinator be unwise enough to continue to take fluid after the first drop of lymph—the true product of the vaccination—has been exhausted.

To the Profession this question is of deep interest, in face of the difficulties of ascertaining how far a vaccinifer of a few months old is absolutely not syphilitically infected. A child may appear healthy at the time when the lymph is taken, but may almost immediately show syphilitic evidences; these may be deferred till a later period, or they may be so slightly marked as to escape observation in the ordinary routine of vaccination.

In many cases, even in three-fourths of those who are born syphilitic, as stated by some authorities, the questionable evidences show themselves within the first two months, but in others they are delayed; hence the question of the compulsory vaccination of children within the present limits is opened up, and whether it might not be desirable to relax the rule and extend the period to six months, or possibly till after the period of dentition if there is reason to have doubts on the subject. This subject is the more interesting as we have no substitute known for vaccination, and so doubtful may the source in the human become, that the advisability of taking the infection from the animal alone urges itself on our attention.

[We should be glad to hear from our subscribers and correspondents of any well-authenticated cases of vaccino-syphilis which have come within their knowledge. In Ireland, we apprehend, they are extremely rare.]

Chaps.

The intense cold has lately made the use of glycerine more common than ever, but a good many people complain of its irritating effects. This is because they use it improperly. They wonder that an article so bland in its general character as glycerine should produce smarting when applied to the skin, as it very frequently does, and the effect sometimes leads to the suspicion of adulteration with some irritating substance. The *Pacific Medical* remarks that the probability is that it is due to the affinity of glycerine for moisture, which it abstracts from the skin so rapidly as to produce the burning sensation. Pure glycerine when mixed with water will raise the temperature eight or ten degrees. To obviate the effect it should be mixed with water before its application. The addition of a small quantity of water will almost entirely prevent the irritation. This hint is, at any rate, seasonable, and will be taken advantage of by many.

The late Mr. Baker Brown.

In our obituary column we have given a detailed account of the most eventful acts in the life of Mr. Brown, and in the long history of his original and successful labours will perhaps be found the most fitting indication of his character.

On account of his lengthened period of suffering, Mr. Brown may be considered to have been dead to the Profession for some years past, and a proper estimate may already have been formed of his value and position amongst the surgeons of this generation. We have been gratified to see that those journals most bitterly opposed to him in his life have behaved with unwonted generosity to him now that he is gone. Alas! that all the praise comes too late. To what end now is the acknowledgment that the operation, which was the cause of his downfall, was "honestly devised as a legitimate resource of surgery?" What now avails him or his young family that he is described as "the consummate artist, the skilful dissector, the unequalled manipulator?" That "perfection of a surgical hand, those slender, long fingers which moved in any direction, and worked with marvellous precision and intelligence in canals and cavities which it had long been thought could never be reached by human hand"—all now are cold and dead, and we look in vain amongst those who are left for a successor of such originality, boldness, and inventive genius.

As a man, Mr. Brown was most kind-hearted and generous, but he sometimes acted without sufficient reflection, was easily provoked, and not sufficiently conciliatory to his enemies. He was an able debater in discussion, and had an eloquence and readiness of words rarely found in our Profession.

The Professorship of Anatomy and Chirurgery in the Dublin University.

The visitors—Sir Joseph Napier as Vice-Chancellor, and Dr. Battersby, Q.C., as Deputy for the Archbishop—sat on Monday and Tuesday week to hear and decide the question at issue between Dr. McDowel and the Board of Trinity College. The controversy, our readers will remember, was as to whether the Board had or had not power to require Dr. McDowel to resign his connexion with the Richmond Hospital or to allocate any part of the dissecting room fees for the endowment of a Professorship of Comparative Anatomy. The visitors were addressed at great length by Dr. Ball, Q.C., M.P., and Mr. Tandy, Q.C., on behalf of the Board, and by Mr. Butt, Q.C., and Mr. Gerald Fitzgibbon, Q.C., on behalf of Dr. McDowel. At the conclusion of the arguments judgment was deferred until Saturday, but on that day it was again postponed, and will be delivered this day. The controversy excites much interest in the Profession, because, should Dr. McDowel's contention be defeated, the power of the Board to alter the position and duties not only of the University Professors but of those of the College of Physicians, will be established.

Dr. Brewer.

Parliament has been opened and is now in full work. On the first night of the session it was pleasant to see Dr. Brewer in his place, he having returned in safety after his late illness.

Female Chemists.

The female students have invaded the preserves of the Pharmaceutical Society, and claim to be admitted to the practice of the "art and mystery" of dispensing, but, as yet, have not succeeded in establishing their position. Having passed the preliminary examination for apprenticeship, three young women—Alice M. Hart, Rose C. Minshull, and Louisa Stammivitz—were presented for election by the Council of the Society. To their admission a direct negative was moved, but after a lengthened debate, the motion was rejected by a majority of one. It was then moved that the subject be deferred until after the election of a new council in June next. On a division, one member refused to vote, and, consequently, the votes were equal, and the Chairman having given his casting vote in favour of the proposal for postponement, it was carried, and the female candidates were adjourned accordingly.

Excessive Mortality in Dublin.

The health of Dublin during the year 1872, as represented by the Registrar-General's annual return, has been very bad. We publish a full abstract of the Report in the Irish Supplement to our Journal, but the principal features of it are worthy of notice here. The registered mortality of the year, 29 per 1,000 of the population, is higher than that of any city of the empire except Cork. By zymotics the deaths were 800 more than the average of eight years, although the cholera epidemic went to swell the latter average. Small-pox cost the community 1,150 lives, and measles 202 as against 26 last year. The importance of these figures is enhanced by the consideration that the Dublin Registration District includes all the suburban districts, in some of which the mortality is only 14 per 1,000.

Ambulatory Ophthalmic Practice.

Amongst the proceedings of the recent meeting of the International Ophthalmological Congress, under the presidency of Mr. Critchett, we find that the Congress was advised, in framing rules for the admission of its members, to adopt the following law :—

"It is enacted that a secret ballot may be held for the exclusion of a member by a demand, signed by at least ten members. *The habitual exercise of ambulatory practice is a cause for exclusion.*"

This proposition formed part of a manifesto which had been drawn up and signed by a great number of members. This manifesto proceeded as follows :—

"In the estimation of the world, oculists have not always been classed as they are to-day. One could formerly see them then going from village to village, from suburb to suburb.

"Thanks to heaven, this pitiable class has disappeared, but the tradition of the travelling oculist is not yet extinguished, and we do not hesitate to admit that we owe to the conduct of those who have not broken off the shameful record, to find ourselves from a professional standpoint less high in position than we should be.

"We still see, even now, practitioners, some of whom occupy lofty and lucrative positions, repair periodically to places distant from their residences, and even to make trips to foreign countries, there to dispute with their fellow professionals who are often more meritorious than they, the practice which supports them."

The practice of "peripatetic ophthalmology," to which this extract refers, may appear to have little interest or reference to us. We refer to it, however, because we are aware that such practices are not unknown to English ophthalmic surgeons, and we desire to express the hope that in the face of a rebuke so incisive we shall no longer "see practitioners, some of whom occupy lofty and lucrative positions, repair periodically to places distant from their residences, there to dispute with their fellow professionals who are often more meritorious than they, the practice which supports them."

Up to a recent period it has been the habit of a leading London ophthalmologist (and one who took a prominent part in this Congress) to make the South of Ireland a vacation feeding ground, and combining relaxation with business and with the help of certain friendly resident jackals, pick up such operation patients as might be disposed to accept the services of the great London eye doctor without incurring the expense of a personal visit to him. For several successive summers, and, for ought we know, up to the present time, the annual peddling expedition was carried out, and we have seen more than one Irish patient who was operated on in Ireland and attended by the oculist in question on such occasions. We trust that the blush which the reading of this manifesto must have brought to the cheek of the gentleman was not observed, and that, taking to heart the sentiment therein conveyed, he will next time be able to take his seat at the Congress with a clear conscience.

The Woolwich Workhouse.

The unpleasant relationship that very frequently exists between the Medical officers and the masters of our workhouses is universally acknowledged. From time to time it has been severely commented on by the press and by the Profession. Occasionally, too, that relationship has been regretted, censured, and "summarily dismissed" from the "governing minds" of that much worried council, the Poor-law Board. Undoubtedly, the Poor-law Board has most arduous, difficult, and diversified duties to execute; nor are we disposed to gainsay the mode—save on occasions—in which these duties are performed by them, but that the pedestals on which it placed the masters of our workhouses (and their immediate subordinates), and the "authority," *swing*, and occasionally the ignorant impertinence exercised by these persons over the Medical officers—backed up and supported by the majority of guardians very frequently—have lately become such formidable "thorns in the side" of the present system of pauper relief as to call for reform, both prompt and incisive ; no one can deny. Therefore, we ask for such revision of that portion of the system as bears on the business relationship of the Medical officers and the masters. At the present time the "system" works this way. Any dunce, master of a workhouse (and many dunces have been from time to time elected, and many of them, too, still occupy the positions), provided he have familiar intercourse with the asinine ears of a section of the guardians under whom he acts, may snub the doctor with impunity, dictate duties to him, cause his satellites to worry him, control the nurses in their attention to his patients, and leave him powerless for action, unless he buckles on the armour of defence, appeals to the Poor-law Board, or calls for an inquiry, and then—Heaven help him ! The church, the law, the land, and the shop interests will *frounce* him by turns, whilst most probably a member of his profession looking at the fun, will enjoy it.

To full-grown bodies—sound and healthy—we seldom if ever prescribe the unrestricted wielding of caudle-spoons, nor do we recommend Mather's feeding bottles, condensed milk, nor even Robb's biscuits indiscriminately, as a rule; yet in the case of the Woolwich infant guardians who now whimper and whine because their Medical officer appealed to the *sensible* authority of the Poor-law Board, having been "Jalloped" and "Botherwelled"—the words have been attributed to the Guardians—by the local authorities, we unhesitatingly recommend *pap* as likely to offer them food for contemplation. But let us not be accused of suggesting the propriety of the nurses essential for this "baby dandling" being supplied from the workhouse, where they have been so very limited heretofore, where all things seem doltish, and where Bumble is "wery wicious" indeed.

Speed at the Press.

We consider ourselves fairly entitled this week to claim credit for "speed at the press." The Pathological and Obstetrical Societies of Dublin met on Saturday night, and from shorthand notes, more than eight columns of matter were transcribed, composed, and printed by Monday night, Sunday intervening. This is speed extraordinary. There were subjects more than usually important presented at both Societies.

We announce with much satisfaction that Dr. McClintock, of Dublin, has resumed his professional practice, being perfectly recovered from his recent severe illness.

We hear that the Government of France has found it necessary to close the Medical school at Montpellier. The cause of this decision is not stated.

The Metropolitan Asylums Board, on the 25th ult., decided that in future all Jewish imbecile patients should be kept at the Leavesden Asylum.

The Regius Professor of Medicine at Cambridge University, Dr. Henry W. Acland, proposes to have a class for clinical instruction at the Infirmary on every Saturday, at 10 a.m., commencing on February 15th.

The Medical Society of the College of Physicians will meet on (this) Wednesday evening, when the following communications will be read :—1. Dr. Grimshaw—"On a Case of Aneurism of the Basilar Artery ;" 2. Dr. Henry Kennedy—"Remarks on the Etiology of Enteric Fever."

From the Registrar-General's last week's returns the number of deaths registered in the metropolis were 1,336. The mortality in London had increased from 18 to 21 per thousand, and Portsmouth, which has been for some weeks far below any other town in England, rose to the same rate, whilst Bristol took its place last week as the healthiest town in England with a mortality at the rate of 18 per thousand.

A series of lectures on sanitary and allied subjects will shortly be given in the theatre of the Royal Dublin Society. The introductory lecture will be delivered by Dr. Stokes, Regius Professor of Physic in the University of Dublin, on February 22nd. Other lectures will follow by Drs. Emerson Reynolds, J. W. Moore, James Little, Professor Haughton, Drs. Hudson, Grimshaw, Mapother, Robert McDonnell, Messrs. Parke Neville, C. E. Drew, and Furlong, Barrister-at-Law.

The College of Physicians of Ireland is about applying for an amendment of their Charter, in order that the subject of election of Fellows by ballot, which was the subject of Visitation last year may be set at rest. On the last day of January a motion was made at a general meeting of the College by Sir Dominic Corrigan—

"That the Fellows of the College are at present wholly a self-elected body, with absolute and uncontrolled power to reject, without any cause assigned, any and every candidate for Fellowship. That it would be of advantage to College itself to introduce into its constitution the principle of representation ; and that to effect this, the Licentiates of the College, or Members and Licentiates as the case may be, should have power, when assembled in convocation on St. Luke's day of each year, to select from among themselves, as hereinafter provided, representatives, to the proportion of one-fifth of the number of Fellows then existing, but not more—it being always provided that not more than two such representative Fellows shall be elected in any one year, and that such Convocation, in so selecting, shall not directly elect, but shall at such meeting of such Convocation select three names, from which the Fellows of the College, on said St. Luke's Day, shall elect two or one, as the case may be, for Fellowship."

The motion was, on a division, rejected by a vote of 14 to 2.

◆

Transactions of Societies.

DUBLIN PATHOLOGICAL SOCIETY.

[SPECIALLY REPORTED FOR THE MEDICAL PRESS AND CIRCULAR.]

Meeting held on Saturday, February 8th, 1873,
Dr. Henry Kennedy in the chair.

AORTIC PATENCY—HEMIPLEGIA—MITRAL OBSTRUCTION—IDIOPATHIC ANEURISM OF ULNAR ARTERY.

Dr. Nixon said, the man from whom these specimens were taken was a wire worker, æt. about 23, admitted into the Mater Misericordiæ Hospital on the 18th of September last. Prior to present illness his health had been bad ; he suffered from three attacks of acute rheumatism, and lately was subject to palpitation of the heart and a feeling of cardiac distress. About five o'clock on the morning of admission he awoke with a violent pain in the back of the head. Notwithstanding this, he dressed and went to his work as usual. The pain in the head became more severe, and about seven o'clock, whilst cutting across some iron rods, he suddenly felt a tingling sensation in the little finger of the right hand. The tingling involved the remaining fingers, extended up the arm and right side of face, then suddenly shot down the right side of the trunk to the right leg. He called for help, walked or limped a few paces towards a fellow workman, and then fell helplessly to the ground. Consciousness was unimpaired. He understood everything said to him. About three hours afterwards Dr. Nixon saw him in hospital. He was perfectly collected, and described to him the nature of his attack: his speech was hesitating and somewhat inarticulate; there was no paralysis of speech; there was neither aphasia nor amnesia; there was simply difficulty of articulation, or, as it is called, "thickness of speech;" there was no paralysis of the tongue. The muscles of the right side of the face were flaccid; it had lost its expression. There was complete motor paralysis of the right upper and lower extremities. On examination of the affected part with the Æstheziometer, I found that sensation was unimpaired. The temperature in the right axilla was 100° F., being nearly a degree higher than that of the left one. There was unilateral sweating of the right side of the face and upper extremity. On placing his hand over the heart he felt a well-marked fremisement, and on stethoscopic examination a loud double bruit was heard at the base. The diastolic bruit was of a peculiarly prolonged character; it gave one the idea of a tongue of fibrine been attached to one of the valves, and thrown into vibrations by the regurgitating blood. The first sound was heard clear and free from murmur; a little to left side of impulse beat, there was marked visible pulsation of the vessels; the pulse was regular, collapsing, and hammer-like; there was not much increase of cardiac dulness; no displacement of apex beat. The urine was normal in specific gravity, and free from albumen. The diagnosis then made was aortic obstructive and regurgitant disease, with the probable detachment of a portion of fibrine from the diseased valves, producing an embolon of the same branch of the left middle cerebral artery. In course of time complete motor power returned to right upper extremity, the face regained its expression, and partial power returned to right leg, but he still "dragged" it after him. The area of cardiac dulness has increased considerably; the heart underwent the displacement downwards and to the left side, and he might say here that towards the end of the case the apex beat was felt on a line with the left nipple, and about one inch below it. About the middle of November, his colleague, Dr. Hayden, in examining the case with him, called his attention to a bruit heard at the apex of the heart. He had no difficulty in recognising it as presystolic in character. It was followed by a clear first sound. Dr. Hayden at this time unhesitatingly diagnosed a contracted mitral orifice, now super-added to the aorta disease. Although he (Dr. Nixon) was satisfied that the murmur heard at apex was mitral and presystolic, yet he found it difficult to conceive that the auriculo-ventricular orifice should have become contracted without any change being manifest in the physical condition of the patient. He was on the whole rather better; there were no pectoral symptoms to speak of, and there still existed the peculiar pulse of aortic patency. Having regard to the pre-existing aortic disease, and the dilated condition of the left ventricle, with the probable large amount of blood regurgitated into it, it occurred to him that this blood, by flapping over the curtains of the auriculo-ventricular valve against the mitral orifice prior to the auricular systole, might in that way obstruct the passage of blood from the auricle into the ventricle during the auricular contraction, and thus develop a bruit before the first sound. Whilst under treatment a new point of interest presented itself. A pulsating tumour was discovered about an inch below the bend of the right elbow, over the site of the ulnar artery. It gave no annoyance to the patient, and its discovery he might say was accidental. The tumour was deeply seated beneath the flexor muscles; it possessed an expansile pulsation, which was arrested by compressing the brachial artery; during the compression the tumour felt soft, and it was reducible in size. When the compression was removed it became suddenly dilated. Over it was heard a loud systolic whiz. The pulse in the ulnar artery was not perceptibly reduced in volume, differing in no respect from the pulse in the opposite limb. On being questioned, he told us that about two months ago he recollected having worked one day unusually hard, from early in the morning until night he was cutting iron wire coils into lengths for garden pailings. The scissors which he used for the purpose was a very blunt one, and it required a considerable and sudden muscular effort to sever the wire. That night he complained of soreness about the elbow, and some stiffness in the hand; he noticed a slight swelling in the forearm, just below the joint. Next day he went to work as usual, and although there was some uneasiness in the arm, he took no further notice of it, nor did he mention anything in connexion with the tumour until his attention was called to it. There was difficulty in recognising the case as one of aneurism of the ulnar artery. One peculiarity existed, viz., that the ulnar pulse was unaffected. During the period of his stay in hospital, the aneurism increased considerably in size; the girth of the forearm, across the site of the tumour, was three quarters of an inch more than that of the opposite limb. He began to complain of cramp, chiefly in the hand. He was unable to close the hand, although at the time the right arm had completely regained motor power, and it was remarked that the little and ring fingers possessed least power, owing to the probable pressure on the ulnar nerve. Under some of the usual plans of treatment the tumour became apparently consolidated, and the bruit in it ceased. The man left hospital on December 23rd. He heard nothing more of the patient until the 25th ult., when he again presented himself at hospital and was admitted. He was extremely anæmic. The face, neck, and legs were œdematous. He complained greatly of cough, accompanied by slight hæmoptysis. There was great tenderness over the region of the liver; it was enlarged to a very considerable degree. He had suffered from an attack of jaundice previously to admission, which, however, had passed away. The urine was small in quantity; its specific gravity was 1·025; it contained a large quantity of lithates, and it was albuminous. The cardiac dulness had greatly increased in extent. The presystolic bruit was audible at the apex. The double bruit was heard at the base. The bases of both lungs were dull and crepitating. On the 3rd February the hæmoptysis, which had ceased, suddenly returned, respiration became greatly embarrassed, the pulse became quick and feeble, the lips were livid, acute agonising pain was experienced about the heart, and about four o'clock on the morning of the following day he died. Dr. Nixon said he should add that on the previous day the mitral bruit had ceased to exist. With reference to the ulnar aneurism, the tumour, though apparently smaller, was soft and fluctuating; its expansile impulse had returned. The bruit was again heard over the sac. In making the *post-mortem* examination he was kindly assisted by Dr. Ward, also by the resident pupil, Mr. Rice. Both lungs were in a state of pneumonia, liver enlarged, congested, and its cells filled with granular fat. The heart, with its contained blood and the thoracic aorta, weighed 31 ounces; emptied of blood it weighs 25 ounces. The right auricle is normal in capacity. The right ventricle is much diminished in size, owing to the encroachment on its cavity by the ventricular septum. The left auricle is somewhat dilated; its walls are normal in size. There is contraction of the auriculo-ventricular opening; it barely admits the extremities of two fingers. The cavity of the left ventricle is immensely dilated, and if they took into account what ought to be the relative size of the mitral opening, he thought he was justified in saying that the auriculo-ventricular opening was diminished one-half. On the auricular surface of the mitral curtains were a number of beads of lymph. The aortic orifice was the seat of exaggerated disease. Large warty vegetations were attached to all the valves, and a large fibrinous mass might be seen hanging down in the ventricle attached above to one of the semilunar valves, below lying free. This tongue of fibrine must, during the regurgitation of the blood, have been carried over against the anterior segment of the mitral valve. The ascending aorta presented some traces of atheromatous degeneration. It was a question to be determined whether the contraction of the mitral opening which existed presented the pre-systolic murmur, or whether it was caused in the way previously surmised. The beads of lymph found on the auricular surfaces of the mitral valves were certainly of themselves sufficient in amount to produce obstruction to the passage of the blood into the ventricle, and he thought, from the dilated condition of the latter, the large reflux of blood from the aorta must have brought the mitral curtains towards each other, thus exposing their roughened auricular surfaces to the passage of the blood, and thus producing the obstructive murmur. On microscopic examination of the heart, many of its fibres presented the appearances of advanced fatty degeneration. He examined carefully the base of the brain for evidences of the cause of the hemiplegia. He found no disease of the vessels of the left side, and though he traced carefully the branches of the left middle cerebral artery, he found no traces of embolic infection in them. On the right side he found a small branch of the right middle cerebral converted into a fibrous cord. Not having found any cause for the paralytic seizure at the base of the brain, he then proceeded to examine it from above downwards, and making on the left side the section of the centrum ovale minus, he observed a dark brownish clot (evidently altered blood) in the middle of the medullary substance. This he found proceeded down the fissure of Rolando, and thence into the lateral ventricle, where it lay immediately on the outer side of the corpus striatum. It lay altogether free of the optic thalamus, which explained the absence of paralysis of sensation. He presented to the Society a specimen of an aneurism of the ulnar artery, the first of its kind shown in the Pathological Society of Dublin or of London. The tumour was situated on the inner side of the ulnar artery, about an inch and a half below the bifurcation of the brachial artery. Lying immediately along its inner side was the ulnar nerve. The sac of the aneurism contained fluid blood.

Dr. Bennett exhibited a specimen of

CONGENITAL DEFORMITIES OF THE CLAVICLE

which he had met with in the course of dissection, and which, he thought, was a case of united fracture of the clavicle in some of its more rare forms.

Dr. Quinlan said the specimen he wished to bring under the observation of the Society was taken from the body of a man who had died in St. Vincent's Hospital on the morning of the previous day. He was admitted on the 20th December, and then did not complain of his kidneys, but exhibited dyspeptic symptoms; and as he said he had been a hard drinker, he was admitted under the idea that he was probably suffering from disease of the liver. An examination of the urine showed it to contain a deposit of casts of tubes and spheroidal epithelium, and it was also loaded with albumen. The symptoms increased steadily and rapidly; pains were felt in the back, the urine became less in quantity, the albumen increased, and the quantity of deposit above described also became larger. The feet now began to swell, and the swelling extended to every part of the body except the neck and head. The case, in fact, exhibited all the symptoms of rapidly-progressing Bright's disease. About three days before death he became gradually stupid and heavy, evidently from eursemic poisoning. The night before his death he became comatose, and died early on the following morning. There was no vomiting nor convulsions. A *post-mortem* examination was made five hours after death. The liver exhibited rather a tendency to cirrhosis. Both kidneys showed the well-known appearances of the waxy form of Bright's disease, but without enlargement. The lower part of each kidney was congested, and was evidently the only sound and working part of the organs left; and in Dr. Quinlan's opinion it was the congestion of this sound and working portion and the consequent sudden and total stoppage of the process of ureal elimination which was the immediate cause of death.

Dr. Kidd brought under the notice of the Society a case of

FIBROUS TUMOUR IN THE UTERUS,

and a report of his observations concerning it will appear in our next impression.

DUBLIN OBSTETRICAL SOCIETY.

[REPORTED EXPRESSLY FOR THE "MEDICAL PRESS AND CIRCULAR."]

The fourth meeting of the thirty-fifth Annual Session, was held on Saturday, February, 8th, 1873, at the College of Physicians. Dr. Sibthorpe in the Chair.

Dr. Kirkpatrick having read the minutes of the previous meeting, they were signed.

The Chairman announced that the Council had recommended the following bye-law for adoption :—"That members wishing to compound, may do so by paying £5 in lieu of annual subscription."

Dr. Kidd gave notice, "that at the next meeting of the Society, he would move the adoption of the bye-law recommded by the Council."

Dr. Kirkpatrick then stated, that he had received a letter from Dr. Morgan, who was to have read a paper that evening on "Specific Inflammation (Dactylitis), of the Hands and Feet in Children," stating that in consequence of the serious illness of a member of his family, he would be unable to attend.

Dr. Kidd then brought under the notice of the Society, the case of "Fibrous Tumour of the Uterus" which he had stated at the meeting of the Pathological Society, and which will be published in our next impression.

Dr. Thomas More Madden asked the indulgence of the Society in reference to a communication which he was to have read on "Certain Improvements in the Long and Short Forceps, and on their use in Midwifery Practice." From circumstances which has arisen, he would be unable that evening to read the paper he had alluded to, but he had prepared a paper on another subject, and if he had the permission of the Society, he would read it instead of the one to which his name was attached on the notice paper. (Hear, hear). Dr. Madden then proceeded to read a paper on

CHRONIC INFLAMMATION OF THE CERVIX UTERI, ITS EFFECTS AND TREATMENT.

In the course of his observations, he said that chronic inflammation of the cervix uteri was the most frequent of all the diseases peculiar to women. Thus, according to Dr. More Madden's experience one-tenth of the patients that attended the Dispensary for Diseases of Women belonged to this category, and in private practice he found this disease quite as prevalent. Amongst the consequences of chronic inflammation of the cervix uteri, Dr. More Madden included endo-metritis, ulceration and hypertrophy of the cervix, menorrhagia, dysmenorrhœa, vaginitis, leucorrhœa, hysteria, and above all, sterility. The treatment of these diseases he regarded as still vague and unsatisfactory, generally protracted, and frequently unrewarded by the cure of the disease. He considered that this was mainly owing to the constitutional causation of these diseases not being duly appreciated in practice. No one conversant with Medical literature could fail, on comparing the medico-chirurgical publications of the present time with those of any former period, to observe the great prominence now given to the study of uterine affections, and the importance attached to them. The questions that not unnaturally arose were, had these diseases really become more common than was formerly the case? or is it, he asks, merely now the fashion of the day to ascribe all obscure complaints to uterine disorder, as it was formerly to attribute them to "the vapours" or the "spleen," or the more modern "nervous and bilious complaints," each of which was, at one time, so prolific a supposed cause of patients' ailments, and more certainly of physicians' fees? Or, have uterine complaints been always as prevalent, though only now discovered by the improved means of diagnosis furnished by modern gynæcological science? Opposite as these doctrines appeared, and warmly as they had been espoused by conflicting authorities, there was, nevertheless, as in most other disputed subjects, some truth, as well as some error in each of them. Uterine diseases were more commonly met with, as well as more in vogue, and above all they were more easily recognised than was formerly the case. The vaginal speculum was unquestionably the greatest improvement that modern science had contributed to this department of Medical practice. It was as essential in the treatment of uterine complaints, as the stethoscope in the diagnosis of pulmonary or cardiac diseases. But it might be abused as well as used, and for his part he could not approve of the indiscriminate resort to the speculum now so general in all cases of suspected uterine disease, and more especially when occurring in young unmarried women. He had had daily occasion, for some years, to induce as many speculums in hospital and dispensary practice as most practitioners, but yet he never regarded himself as justified in so doing in any case in which the instrument could be possibly dispensed with. Many cases had come under his notice, in which, patients having been previously treated for ulceration of the os uteri, insisted on being "examined," and when, as not unfrequently happened, he did not think this procedure necessary, these persons were dissatisfied, and considered themselves neglected. And yet in a large proportion of such cases, by simply paying attention to the general health of the patient, ordering the free topical use of cold water, and enjoining total abstinence from marital relations, all the symptoms would subside, and the invalid would regain perfect health, the *mens sana in corpore sano*, far more completely and rapidly than if the parts had been subjected to the mechanical irritation of repeated examinations with the speculum, and so aided in keeping up that morbid concentration of the imagination on the supposed seat of the disease, which is so common in such cases. But, whenever extensive disease of the os or cervix uteri exists, the use of the speculum is, of course, indispensable. Dr. More Madden then described the symptoms of uterine disease, and next described the causes of the prevalence of these affections. Of these, he said: "In considering the causes of chronic inflammation and ulceration of the uterus and especially of the cervix uteri, undue importance is now-a-days attached to the local exciting causes of these affections, whilst the constitutional predisposing causes which I consider as the *fons et origo maloren* are disregarded. This matter is one of considerable practical importance, for if the views herein set forth as to the constitutional causation of local uterine diseases attended by inflammation, ulceration, sterility, and other organic and functional derangements be right, the treatment of these affections will be materially changed, improved, and simplified. The scrofulous diathesis is, in my opinion, and according to my experience, one of the most common predisposing causes of the diseases that form the subject of the present paper. This fact, as far as I am aware, is completely ignored by all the recognised authorities on the subject, and my chief object in coming before the Obstetrical Society with this memoir is to call attention to the connection between struma and the most common forms of uterine disease, in the hope of thus contributing to a more satisfactory and rational plan of treating these complaints. My attention was first called to this point by noticing that amongst the large number of patients suffering from chronic uterine affections, such as leucorrhœa, endo-metritis, inflammation, ulceration, or hypertrophy of the cervix uteri, ovarian pain, sterility, repeated miscarriages, derangements of menstruation, &c., that come under my observation at the Dispensary for Diseases of Women attached to the Lying-in Hospital a very considerable proportion was obviously of well-marked scrofulous habit; in many instances they suffered from actual scrofulous disease of other parts, and in others I was able to trace the influence of a hereditary scrofulous taint. In these cases the uterine symptoms, the character of the inflammation, the form of ulceration, and the nature of the discharge were all impressed with the scrofulous type. The constitutional condition of the patient being thus strumous the local uterine disease is precisely analogous to the scrofulous inflammation of the conjunctiva or phlyctenular ophthalmia of strumous children, being attended by a similar tendency to produce excoriation or phlyctenulæ of the mucous membrane, and, by a somewhat similar glairy discharge, and being as intractable under ordinary treatment. Many of the symptoms of scrofulous inflammation are generally present in the cases under consideration; in these the inflammatory action is as insidious in its first encroachment as chronic in its course, as obstinate in its duration, and as difficult to cure. Like all other forms of scrofulous inflammation, that affecting the cervix uteri is peculiarly apt to lead to the formation of ulcerations of the characteristic strumous appearance, irregularly circular in shape, superficial in depth, pale and flabby in aspect, possessing little natural sensibility, but occasionally angry and irritable, tedious beyond patience when neglected or maltreated, and best cured by the treatment appropriate to other diseases of the same character. The treatment of the complaints now under consideration may be divided into 1st, the topical medication required by the widely varying forms of inflammation, hypertrophy, or ulceration that may be present in each case; and 2ndly, the cure of the constitutional derangement which always accompanies, and I believe very frequently causes, the local disease. At the present time almost exclusive attention is paid to the former, the latter being as generally neglected. For my own part whilst I attach due importance to the local treatment of all uterine diseases, yet I am fully convinced by experience that the reason the cases we are now considering are generally so tedious and protracted in their cure is, that the greatly improved local treatment now relied on is not assisted by proper constitutional remedies. I shall, therefore, in the first place briefly allude to the constitutional treatment I consider necessary in these cases, for, as I have just stated, I regard chronic inflammation of the uterus and its results, including ulceration, as a consequence of a coincident constitutional disease and therefore not to be cured by local treatment alone, except in those rare cases in which it is due to local mechanical irritation. In accordance with the views already expressed as to the frequent connection between chronic uterine complaints and the scrofulous diathesis, I would strongly urge the advisability of giving a fair trial to anti-strumous remedies and regimen in the cases now under consideration. I have seen numerous instances of what I regard as scrofulous ulceration of the cervix uteri thus cured without any local application beyond that of a little tincture of iodine and the use of vaginal injections. My experience of their use would lead me to recommend the simple preparations of iodine given in the small doses originally ordered by Lugol, such, for example, as the one-eighth of a grain of iodine with one-fourth of a grain of iodide of potash in preference to the larger doses of its compounds now generally prescribed. In case where symptoms of anæmia predominate, the various combinations of steel with iodine are of singular benefit, all symptoms of uterine disease often disappearing under their use without any local treatment whatever. Of all the remedies I have tried in these cases I have found no one so generally serviceable as a mixture of equal parts of cod-liver oil and syrup of iodide of iron. Scrofula, although a frequent, is by no means the only predisposing constitutional cause and accompaniment of the diseases we are discussing, and hence, in a large number of cases we must have recourse to other constitutional treatment to alter that morbid state of the system which is the remote cause of the existing uterine congestion or inflammation. This must be effected by a modified antiphlogistic treatment, conjoined with rest, tonics, and sedatives, as well as the local use of baths, or injections, caustics, astringents, counter-irritants, or local depletion, according to the special requirements of each case. As a rule, chronic inflammatory disease and its effects of the uterine whether limited to the cervix or affecting the entire organ when not of scrofulous origin requires the administration of mercury, which is best given in the form of small doses of the perchloride, one-twenty-fourth of a grain three times a day, in the tincture or infusion of bark. Notwithstanding the prevailing scepticism as to the efficacy of medicines in these chronic uterine affections my experience of many cases has fully convinced me that although the local symptoms may subside for the time under purely local treatment the patient is more quickly as well as more permanently cured by the administration of constitutional remedies, such as that just referred to, whilst due attention is, at the same time, paid to the local treatment of the ulcerated or inflamed part. The prevailing type of chronic uterine complaints, like that of all other general diseases of the present time, is essentially asthenic and require the administration of tonics in almost every instance, and more especially the preparations of steel, iodine and quinine combined, when circumstances admit of it, with change of air and mineral waters. The curative effects of change of climate and of mineral and thermal waters in cases of chronic uterine disease as well as other disorders is a subject on which I am entitled to speak with some confidence, having given my attention to it during several years of travel and clinical observation in the health resorts of the Continent and the Mediterranean shores of Europe and Africa, as well as at the spas of Germany, France, and Italy. No class of remedies is so useful and so generally appropriate in all chronic uterine diseases of an inflammatory origin, and more particularly when producing ulceration or hypertrophy of the cervix uteri, as mineral and thermal waters used at their sources, and hence conjoined with change of climate. These maladies are peculiarly chronic in their course, and almost imperceptibly produce their ultimate result, namely, the causation of structural or organic mischief." Dr. Madden then proceeded to point out seriatim the various spas suitable for the treatment of the different forms of chronic uterine disease. With regard to the local treatment of cases of chronic inflammation, ulceration, and hypertrophy of the cervix uteri, he fully admitted the great importance of local treatment in these cases. Vaginal syringing, either cold or tepid as may be most agreeable to the patient, was the first method of using any topical remedy in uterine diseases, and it remained one of the most useful and indispensable. Various fluids have been proposed for this purpose. In cases of mere inflammation or congestion without ulceration or bad leucorrhœa, cold or tepid water or infusion of chamomile thrown up by a syphon vaginal syringe, in quantities of a pint or two twice daily, was, perhaps, the most useful. Where an astringent is required the decoction of oak bark, with or without sulphate of alum, ʒj. to the pint, or a similar quantity of the compound powder of catechu mixed in warm water, strained and used cold, or a very weak solution of the perchloride of iron generally answered. If the discharge be offensive, a weak solution of permanganate of potash or of carbolic acid might be tried, and if pain be the prominent symptom, a little liquor opii (ʒj. ad O) might be resorted to. These cases seldom come under observation till the disease had passed from the stage of congestion or inflammation into that of ulceration. If, however, the cervix was found congested on examination whether ulceration was present or not, it might be relieved by a few punctures with a sharp bistory in the congested organ, or with less trouble to the patient, and generally equally effectually, by the application of a plug of wadding saturated with glycerine to the os and cervix uteri. In this way it acted as a powerful depletant, and on the removal of the plug, which should be withdrawn within twenty-four hours, the part which might have previously been congested and angry-looking would be found pale and of normal colour, or if ulcerated, the abraded surface will appear perfectly clean and healthy-looking. It need hardly be observed that these effects were not permanent; but the repetition of the same application would for a long time continue to produce similar results, until either the remedy lost its power or the disease was cured. In the majority of cases of simple ulceration of the os and cervix uteri a free application of a strong tincture of iodine twice a week was the best and most speedy curative local application that can be made. If that failed, as it sometimes would, the solid nitrate of silver or a strong solution of this salt may be similarly employed. Whenever there was any well-founded suspicion of the ulceration being of syphilitic origin, the acid nitrate might be resorted to, but required to be most cautiously used. In the severer cases of granular ulceration extending, as was frequently the case, from the os through the patulous cervical canal to the body of the uterus, a single application of the fuming nitric acid, pressed firmly against the diseased surface and passed through the cervix into the cavity of the uterus by a wire thinly coated with cotton wadding dipped in the strong acid, when aided by proper constitutional treatment, efficiently destroys the most angry and obstinate ulceration, leaving a clean, healthy, granulating surface as soon as the eschar had fallen, and seldom required to be used a second time if properly applied. With regard to the potassa cum calce, in the few cases in which he had seen it employed the results were not such as would induce him to recommend its use. Of the stronger caustic—the potassa fusa—advocated by Dr. J. H. Bennett and by the late Sir James Simpson, his experience led him to coincide entirely with Dr. West, "that when adopted it is usually either out of place or superfluous." He had seen great injury done in some cases which came under his observation, in which bolder practitioners had used caustic potash freely to cauterise an ulcerated os uteri or to reduce an enlarged cervix. In two cases he was obliged to attempt to restore by dilatation the canal of the cervix, which had been almost obliterated by the improper application of caustic potash, and one in which the vagina was thus occluded. Nor were these the only evils which might follow the employment of this heroic remedy. He had had to treat acute metritis produced in this way, and he therefore had not thought himself justified in using a remedy liable to produce such consequences when other agents, equally powerful but less dangerous, could be employed. Hypertrophy of the cervix uteri considered as a cause of sterility had attracted more attention than it deserved, and a variety of heroic surgical procedures had been proposed and were practised for its removal with this view. Those included amputation of the enlarged cervix, as recommended by Dr. Marion Sims, the application of potassa fusa or of the potassa cum calce for the purpose of melting down the enlarged cervix as advocated by Dr. J. H. Bennett, and the employment of the actual cautery as practised by French surgeons. Now, in his (Dr. Madden's) opinion, all these procedures were, as a rule, not only useless but injurious in the majority of instances of hypertrophy of the cervix uteri, though each of them might be necessary and beneficial in extreme cases and under exceptional circumstances. Dr. Madden concluded his excellent paper as follows:—"The practical conclusions which I would venture to submit to the consideration of the learned Society which I have the honour of addressing these observations to, as the result of my experience of chronic uterine disease, and on which I trust to elicit the opinions of those who have had such opportunities of investigating the subject, are briefly as follows:—1st. That chronic inflammation of the uterus, and especially of the cervix uteri, producing hypertrophy and ulceration, is in the majority of cases occasioned by constitutional causes, one of the most frequent of which is the scrofulous diathesis. 2nd. That these diseases require constitutional as well as local treatment; the constitutional treatment required has been already discussed, and I would again urge the benefits derivable in these cases from the use of the mineral and thermal water I have already spoken of. In many cases of chronic uterine inflammation and ulceration of the cervix uteri, the inflammation may be subdued and the ulcer cicatrized by local application alone, but whenever general treatment is not combined with the local measures depended upon, the inflammation subsides or the ulceration heals much more slowly, and the disease is far more liable to recur within a short time than is the case when suitable constitutional remedies are also resorted to."

Dr. LALOR said that about twenty-five years ago he knew of a case of dysmenorrhœa occurring in a strong, healthy looking young woman, the daughter of a farmer living in the country, and who had had one or two attacks of rheumatism, which ended in rheumatic diathesis, and it certainly left the impression on his mind that the dysmenorrhœa arose and was caused by the rheumatic attacks. The cure in that case was effected with iodide of potassium, and that was in his opinion the best treatment. There were many diseases which were called constitutional, but which were as a matter of fact local disorders, and their origin, nature, and mode of treatment were strictly constitutional.

Dr. JOHNSON said, in the course of his experience he found the mercurial treatment most beneficial. He agreed with Dr. Madden that the abuse of the speculum should be decried.

Dr. STEWART said he believed that scrofula was as much the universal disease of the body as sin was of the mind.

Dr. KIDD believed he might say they had at least two schools since gynæcology was first studied; they had those who looked upon the disease of the uterus as a manifestation of constitutional condition, and they also had those who looked upon the constitutional condition as being a result of local disorder. Dr. Kidd then referred to cases of uterine disorder in which constitutional treatment had been adopted without any good result following. He believed it was quite true that a scrofulous constitution would manifest itself in the uterus as well as in other organs, and if they had scrofulous symptoms they must treat the disease constitutionally, and, at the same time, not forget the local treatment. He did not agree with Dr. Madden when he said that it was unsurgical and unmedical to use caustic potash, as he was of quite an opposite opinion.

Dr. BYRNE said he did not think some of the constitutional remedies recommended by Dr. Madden were available, except in a certain range of society, unless they sent the majority of their patients to Portobello. (Laughter.) He had found the greatest benefits result from the application of strong nitrate of silver to the interior surface. Cod-liver oil and iron would, no doubt, be very beneficial in some strumous cases, but such cases are very rare.

Dr. HENRY KENNEDY mentioned several cases in which constitutional means were used with success. In some cases, of course, local treatment was beneficial.

Dr. MADDEN, in the course of his reply, after correcting one or two errors which had been fallen into by previous speakers with reference to remarks he had made, said he was convinced that the local treatment, in order to effect a permanent and speedy cure, must be aided by constitutional treatment. He believed that constitutional treatment was seldom resorted to in that city. They were generally regarded as local abscesses. He agreed with Dr. Johnson, and said he had seen great advantage derived from those cases which had been cured during the time he (Dr. Madden) served under Dr. Johnson; and he believed that what Dr. Lalor had said respecting the connection of rheumatism with the disease under discussion was perfectly correct.

Obituary.

ISAAC BAKER BROWN, F.R.C.S.

In our issue of last week we noticed briefly the death of this most distinguished surgeon, and now proceed, according to our promise, to give a detailed memoir of the more important events of his life.

Isaac Baker Brown was born at Colne Engaine on the 8th of June, 1812. He was of good parentage, his father being a gentleman of considerable property, managing his own estate, his mother the daughter of the celebrated Dr. Boyer, who was head grammar master of Christ's Hospital in its most famous days, when S. T. Coleridge, Charles Lamb, Bishop Middleton, and Leigh Hunt were pupils.

Educated at a private school in Halstead, he was early apprenticed to Mr. Gibson, practising in that town and with a good surgical reputation in the county. Young Brown had always shown a taste for every occupation in which manual skill is required, and he had, as it were, articled himself to nearly every mechanical trade. He had taken lessons at the village shops, in bootmaking and tailoring, he could make many musical instruments, he understood the whole internal mechanism of a watch, and was able to take one to pieces and put it together again in the most workman-like manner. Moreover he could shoe a horse as well as a farrier, and from continual attendance in the village slaughter house, gained considerable knowledge in comparative anatomy. Mr. Gibson, though in large practice, allowed his pupil many opportunities of prosecuting his anatomical studies, and young Brown arrived in London with a completeness of preliminary knowledge very rare at that period, and still less so now when youths commence at hospital crammed with knowledge on abstract science, but with such an ignorance of therapeutics and anatomy that a prescription is as Hebrew, and the Lecturer on Osteology speaks to them in an almost un-known tongue.

Having entered at Guy's and become the house pupil of Mr. Hilton, the subject of our notice soon achieved distinction and gained the Astley Cooper Prize in Anatomy, being at that time the youngest pupil in the class. Mr. Brown passed the College of Surgeons in 1834, and in the same year became a licentiate and member of the Apothecaries Hall. He then, being married, settled in general practice at the West End in partnership with the late Mr. Griffiths. But, great as was his success in this sphere, Brown was destined for greater things. When at Guy's he had read a paper on "Ovarian Disease," which had attracted notice and he had always taken the greatest interest in Diseases of Females. He was a most successful operative accoucheur, and was a strong advocate for turning, or the use of forceps, when the precept laid down by the authorities was to leave everything to nature. As early as 1844, he commenced writing papers in the *Lancet* on various methods of relieving Ovarian Dropsy by tapping, by tapping and pressure, by injection of iodine, by excision of a portion of the cyst, and the establishment of a fistulous opening, and by medicinal treatment. In some of these plans, notably in that of tapping and pressure, he had some success, but he gradually became convinced that nothing but extirpation of the tumour could offer a fair hope of permanent cure. At a very early period, therefore, Mr. Brown became an ardent ovariotomist, when the title instead of conferring distinction, made the holder of it subject to the strongest condemnation of the Medical press, and of some of the most distinguished surgeons,—*e. g.*, Mr Lawrence—of the day. Mr. Brown performed the operation of making an artificial oviduct as early as October 1847, but he did not perform ovariotomy until 1851. His first three operations were unsuccessful, and he had also performed five other operations, three for formation of an artificial oviduct, and two of partial extirpation with three recoveries and two deaths. He had thus opened the abdomen eight times with the result of having lost five of his patients. The next patient that presented herself was his own sister. Supported by an early advocate of ovariotomy, Mr. Samuel Lane, Mr. Brown decided to operate March 29, 1852, and with complete success, for the lady has since married, has had several children, and is still living. At the present day with the wonderful results of Dr. Keith of Edinburgh, and Mr. Spencer Wells, the statistics of the pioneers of ovariotomy, such as Dr. Clay, of Manchester, and Mr. Baker Brown, appear but moderately successful. It must be remembered, however, that the after-treatment of all operations is much more scientific now than it was twenty to twenty-five years since, and it is doubtful whether any operation has taught so much the value of absolute cleanliness as a preventive of septicæmia, as the one under consideration. The statistics of Mr Baker Brown during the last ten years of his life, will compare with those of the most successful operator, and are even more favourable than a contemporary has made them. In the second edition of "Ovarian Dropsy," published in 1868, the results are given of 111 cases. We have had the opportunity of examining the case-book of the London Surgical Home up to the termination of its existence at Notting Hill. We there find that nine further cases were treated, all of them successfully, thus making 120 cases in all. Of the first 50 cases operated on by Mr. Brown, he lost 24, whilst of the remaining 70, commencing in Jan., 1863, he had only 11 deaths, and 59 recoveries; in other words 84·25 per cent. of recoveries, and only 15·75 per cent. of deaths. The last 19 cases of this series were all successful. Mr. Brown commenced the use of actual cautery for division of the pedicle and of adhesions in his 67th operation, and his last 53 cases were so treated, with the result that only five died, *i. e.*, with 91·6 per cent. recoveries. In Peaslee's classical work on "Ovarian of Disease," we find that the result of Dr. Keith's practice (which commenced in 1864) up to the end of 1871, was 81·61 per cent. recoveries out of 136 cases, and that of Spencer Wells (which dates from Feb., 1858) up to the same period, showed 74·54 per cent. of recoveries, out of 440 cases. These statistics were supplied by the operators themselves. We have entered thus minutely into this question, because the work of the early labourers in this great surgical field has not received sufficient acknowledgment, and this has especially occurred in the case of Mr. Brown, who freely and fully published his failures as his successes.

To resume our biography, in 1848 Mr. Brown became a Fellow of the College by examination, and having at that time become conscious of the great want of hospital accommodation in the west and north-west of London, he took the initiative in the foundation of St. Mary's hospital. The first committee took place in his dining room, and at the dinner held the evening after the first stone was laid, Prince George of Cambridge, proposed the health of Mr. Brown as "Founder of the hospital." Mr. Brown was appointed Surgeon-accoucheur to the hospital at its commencement, and on the formation of the school he was appointed Co-lecturer on Midwifery, &c.

We have dwelt at great length on Mr. Brown as an ovariotomist, but it was as a surgeon in all kinds of plastic operations on the female organs, that he pre-eminently shone. When in 1854 he published his work on "Surgical Diseases of Women" (which went through three editions), he at once opened up a branch of surgery almost entirely neglected previously, and he attracted to his *clinique* not only visitors of distinction from abroad, but surgeons of eminence from the provinces and from other metropolitan hospitals. The artistic skill and beauty with which he operated, elicited unanimous admiration, and his successes in his special department have never been equalled. His plan of incising the os and cervix uteri in cases of hæmorrhage from intra-uterine tumours has been followed by the best results, and is now largely practised. In the year 1858, Mr. Brown left St. Mary's, having shortly before established the London Surgical Home, an institution that treated in the ten years of its existence nearly 1,200 cases, all of them of a surgical character, and almost all under the care of Mr. Brown. In the year 1861, he was visited by the eminent French surgeon M. Nélaton, who resided some days as his guest, having come to London expressly to witness his practice as an ovariotomist. Mr. Brown performed on this occasion three ovariotomies in succession in one day. M. Nélaton saw him also operate on two other cases, and saw several under course of recovery after operation. On his return to Paris he gave an account, in a clinical lecture, of all he had seen; and it is not too much to say that through Mr. Brown's enthusiasm and success M. Nélaton introduced ovariotomy to the favourable notice of the Profession in France.

In 1865 Mr. Brown was elected President of the Medical Society of London, and here he appeared to have reached his zenith. He was certainly one of the most hospitable, dignified and popular presidents of this most ancient of Medical societies.

In the following year, he published his remarks on the *Curability of some Forms of Insanity, Epilepsy, and Hysteria.* Subsequently to the publication of this book, occurred the arraignment of Mr. Brown before the Obstetrical Society. The whole sad affair is too fresh in the memory of all to require to be re-opened. Suffice it to say that after the verdict of the society, his practice rapidly diminished. He made several endeavours to retrieve his fortunes, but successive attacks of paralysis entirely shattered his health, and for the last year he has been utterly helpless.

He was suddenly attacked on Saturday the 1st instant with vomiting and headache. He soon became unconscious, and died on Monday morning, in the 61st year of his age. The necropsy showed recent and old clots in the brain, and partial softening of its substance.

Mr. Brown was twice married. By his second wife, he leaves three young children. His young son is a candidate for the foundation of Epsom College, and it is to be hoped that the Profession, remembering only the good work his father has done, and how generous a supporter he was of all Medical charities in his prosperity, will earnestly support the candidature.

Correspondence.

THE ALLEGED DEATH BY NITROUS OXIDE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The case of death at Exeter, supposed to have been from the effects of nitrous oxide gas, reported in your number of 29th inst., will doubtless give rise to considerable discussion, and afford a convenient stand-point for the opponents of the gas, and upholders of chloroform to rush into print, as Dr. C. Kidd has already done in the *Daily News*, in defence of their favourite theories. Meanwhile, we merely wish to point out that in the absence of any *post-mortem* examination it is impossible to form any positive conclusion as to the actual cause of death, and the suggestion of Mr. Arthur T. Norton (F.R.C.S.) in the *Evening Standard* of yesterday may point very nearly to the truth—viz., that the death was probably not brought about by the gas itself, but that the production of hæmorrhage by an unsuccessful attempt to extract the tooth, followed by a second inhalation of the gas, leads to the belief that blood must have been drawn into the larynx, the symptoms described being those which would occur under such circumstances.

There is one other point upon which we are as yet unenlightened, and that is as to the purity of the gas used.

As the nitrous oxide gas has now been administered in this country for upwards of four years, in many hundred thousand cases, without any previous fatal accident having been recorded, it is impossible to avoid the conclusion that there must have been something further in the Exeter case than appears in the newspaper report to account for its fatal issue.

We remain, Sir, your most obedient servants,

GEORGE BARTH AND CO.

26 Duke Street,
Bloomsbury, Jan. 30, 1873.

THE USE OF ETHER IN OPHTHALMIC SURGERY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read with considerable interest a letter by Dr. Jacob, of Dublin, commenting on a letter of mine recently published in the *British Medical Journal* on our experience of the use of ether in ophthalmic surgery. Dr. Jacob tells me that I don't give it the right way, but I give it exactly as Dr. Jeffries showed us last summer and as he described as the method in use in America. Now there is good evidence that ether *given in this way*, if this is really the American method, *is* safer than chloroform; but is there as yet any evidenee that ether given without air and respired over and over again is even as safe as chloroform? Dr. Jacob tells us of forty-two successful cases, but I think a new mode of giving an anæsthetic should be considered as on its trial until, say 10,000 cases can be quoted; then if the average of success is higher than by the method already in use it should be adopted. In the bichloride of methylene we have an anæsthetic so very convenient in eye surgery that I should be unwilling to give it up in favour of any other until that had been proved by other people's experience to be decidedly safer than it is. I have had a comparatively large experience of this agent (about 2,800 cases) and have never been seriously alarmed by it, but I do not think it is absolutely safe, and would willingly adopt ether by Mr. Morgan's inhaler if it can be proved to be safer, but I don't think it follows that because ether is very safe given as Dr. Jeffries gave it, *therefore* it must be safe to give it as Mr. Morgan recommends, though this may, perhaps, prove to be the case also.

I am, Sir, your obedient Servant,

T. C. MORGAN, House-Surgeon.

Royal London Ophthalmic Hospital,
Blomfield Street, Moorfields, E.C.

ENGLISH AND IRISH PRACTITIONERS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Why are our North British *confrères* so marked in their silent contempt of Irish Medical and surgical sciences? It can hardly be through ignorance while we are ably represented by the press in your pages and those of the *Dublin Journal of Medical Science*. Can it be from jealousy? Hardly. The country that has given such a brilliant galaxy of stars to the Profession, on whose shores flourished the Gregories, Munroes, Alison, Cullen, and Syme in days gone by, and who have still amongst them Bennett, Watson, Spence, Lister, Pirrie, Keeth, McLleod, and many others known to fame, need not grudge a fair acknowledgment of the services rendered to mankind by the Irish contingent of the Profession. These remarks are elicited by reading an article in the *Edinburgh Review* of October, 1872, "On the Progress of Medicine and Surgery."

The writer properly looks on the introduction of anæsthetics, of the lithotrite, and ovariotomy as the three brilliant triumphs of the last half century, and gives full and due praise to the great men who distinguished themselves in those several subjects. But why omit the discovery by our Transatlantic brethren of the use of ether, by which they still stand so firmly, or the efforts of an Irish surgeon to maintain its superiority to chloroform? Why omit the efforts made by Crampton, Cusack, Smyly, and others to improve the lithotrite before Fergusson or Sir H. Thompson had commenced using it? Still, those of omission might be parpardoned, but when the author comes to claim conservative surgery and the cure of aneurism by compression as triumphs of Scotch and English surgeons one feels astonished at either his ignorance or forgetfulness. Did he never hear of Butcher's resections, or the many reports from time to time from almost every surgeon of repute in Dublin of successful operations based on the great principle of conservation. Amongst others Stokes's improvements on the operation of hare lip and cleft palate. In fact, conservative surgery is the glory of the Irish school, carried to its greatest perfection in the treatment of aneurism by pressure, a battle-ground on which Irish surgeons maintained their position against the ablest Scotch and English practitioners, and with Irish surgery the triumph remains. But the author, in alluding to this subject, writes—"Long since pressure was used by Quettani and others, so that its renewal by Dr. Hutton, of Dublin, may be considered a mere revival, though it were practically a rediscovery. The success of his practice set *English* surgeons on the track, and ligature is now no longer used where pressure can be applied." Not a word of the laborious study of the disease, its pathology and cure, by Bellingham and Tuffnell, of the ingenuity of Caste, or the constant preference of this mode of treatment by every surgeon of repute in Ireland. In fact, this triumph of surgical art is peculiarly Irish, and has always been more successful in their hands than elsewhere.

The writer must know that the Irish school has a host of honoured names who have worked in the foremost places in the perfecting of all these triumphs of surgical art and in others of Medical science. To enumerate the living would, perhaps, be invidious, but Crampton, Cusack, Colles, Smyly, Graves, Kirby, and Hutton are names not to be lightly forgotten, and one remains amongst us who, with his colleague, Graves, was the means of introducing the use of the stethoscope into Great Britain, whose name, as a clinical teacher, is known throughout the world, and whose honoured years are still spent in the service of his fellow creatures and the advance of science one whom we all desire may be spared to us for many years to come.

Ireland can boast of a host of hospital surgeons whose future we feel sure is pregnant with professional triumphs; and we have the versatile talents of Haughton to teach the rising generation of students to acquire knowledge, to cultivate science for their own worth, and to practice an honourable and humane profession like *gentlemen*, not *philistines*.

I am, &c.,
Your obedient servant,
JAMES MARTIN.

Portlaw, co. Waterford.

THE PROPOSED NEW CHARITY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The letter of "A. W.," which recently appeared in your columns advocating the claims of a hospital for those who are either idiotic or unfortunate enough to be suffering under an attack of litigation, is one which ought not to pass unnoticed.

It is, let us hope, the commencement of a great movement, it has opened a small door, or rather lifted a small corner of a huge curtain, which hides a scene of abject suffering and patient endurance of lingering lasting misery of years, the more terrible because so carefully concealed. The victims themselves generally suffer in silence, because hopeless, while it is obviously to the interest of those who have actively caused their woe, as well as of those who have passively or carelessly looked on, to be quiet themselves, and as far as possible to keep others so. But how long shall we content ourselves by merely saying "these things ought not to be." Why in the name of Justice—Justice, I say, Sir, not law—does not somebody or somebodies rise up and say "verily these things shall be no longer." I do not wish to speak of law reform or any such gigantic, hopeless question, my idea is quite simple and I think as practical as it is simple, all classes must unite to correct a terrible abuse, which can only have existed because public attention has not been fully drawn to it. Let us proceed without loss of time to the formation of a charity which shall make us at once the wonder and the envy of the whole world. Let us put aside that melancholy and cruel old farce that justice is equally open to the rich and the poor, or rather let us change it from a great farce to a great fact; let us take away from the poor man his bitter rankling feeling that justice can never be his, solely from his lack of means to purchase it, Let us go to visit the suffering, starving families whose heads, whose bread-winners have been suddenly struck down by an attack of acute involuntry litigation, let there be an institution where they may be received, succoured, and cured, as they would now be should the attack be one within the range of Medical skill, let us open at once a subscription list, be assured that my mite shall be forthcoming, and let us commence at once to build, confident of the support of a generous public. There is some vacant ground in the neighbourhood of Carey Street, which appears to be of no use to anybody, to erect a building there where law should be administered gratuitously would be a noble example of the disinterestedness of the legal profession. There let the first of many such institutions arise, there could be no difficulty as to its officers. The Attorney-General, the Solicitor-General, and a limited number of our leading Q.C.'s. would form the consulting staff, these gentlemen, beside being somewhat advanced in years, would, from their many engagements, be prevented from the active duties of the wards, but their opinion would at any time be freely given to any unfortunate in need thereof, the other appointments to be filled as "A. W." suggests, the chosen candidate to be elected by ballot, as the applications at first for posts at once so lucrative, and so honourable, would in all probability be overwhelming.

This good work I would at first intend to apply to the poor only, but depend upon it before very long the middle, and possibly the upper, classes would begin to perceive and to avail themselves of the benefits of this charity. Thus would all classes be brought under the (then) beneficent wing of the law; thus would justice become really equal to all; and last, but not least, our legal brethren, while fully occupied, would find their profession as remunerative, as little laborious, and as comfortable as the sister profession of medicine.

I am, Sir,
Your obedient servant,
M.D.

Medical News.

Royal College of Physicians of London.—The following Fellows, recommended by the Council, have been appointed to fill vacancies in the Council:—Drs. Herbert Davies, George Johnson, Wegg, Murchison, Stewart, and Martin. The following gentlemen, having passed the required examinations, were admitted members of the college on the 30th ult.:—William Williams, M.D., Queen's University, Ireland, of Bennarfawr; Norman Moore, M.B. Cantab, of St. Bartholomew's Hospital; and John Penn Hartree, M.D. Cantab, of Grosvenor Street.

We are requested to state that Mr. Prescott Hewett, the newly elected President of the Clinical Society, will deliver the annual address on Friday next at 8.30 p.m.

General Medical Council.—It is stated that the Chancellor of the Exchequer has offered for the accommodation of the Medical Council handsome and commodious apartments.

Yellow Fever.—By the last mail we learn that yellow fever of a fatal form was prevailing at Sierra Leone.

Lord Hatherley, the late Lord Chancellor, according to a daily paper, lately underwent an operation for cataract.

One-third of the total head of horned stock in Cheshire died last year from the foot-and-mouth disease.

Royal College of Surgeons of Ireland.—At the quarterly examinations held on Jan. 19th, 25th, 28th, 29th, 30th, and 31st, the following gentlemen obtained the licence to practise surgery:—Francis T. Bray, Joshua G. Brereton, Annesly C. De Renzy, James V. Fitzpatrick, John E. V. Foss, Mathew P. Healy, Albert T. Hickson, Thomas Hickling, Christopher J. L. Hughes, Kingston D. Kirkwood, Edward C. Levinge, Michael Loughnan, James R. M'Innery, Alfred H. Martin, John M'Creery, Chas. Moutray, Edward J. Mulligan, Horace T. Newman, Michael P. O'Connor, Henry W. Oulton, Joseph Power, Hy. A. W. Richardson, John J. Redmond, George Rogers, James Shaw, George L. B. Stoney, Mark S. Todd, Joseph H. Wolfenden.

Cambridge University.—The following degrees were conferred on Friday last:—*Bachelors of Medicine.*—Charles Edmund Oldman, Trinity; John Henry Cardwell, Caius; Richard Evan Day, Emmanuel; Wm. Fisher Macmichael, Downing; William May, and Henry Drury Cust Nun, Corpus Christi.

Royal Free Hospital, London.—The annual meeting of this charity was held on Thursday at the hospital, Gray's Inn Road, and from the report of the Committee of Management it was seen that the support received during the year from legacies had been unusually large, and had amounted to £5,600. Another munificent donation of £1,000 from D. G. had been received, being the fourth similar donation from the same benevolent individual. The number of in-patients admitted during the year was 1,451, and the number of out-patients 46,299. The total income had amounted to £12,572, and the expenditure to £7,968, leaving a balance of £4,780.

Metropolitan Small-pox Hospital, Highgate.—The half-yearly general court of governors of the above hospital was held on Friday last. The report stated that the long-continued epidemic of small-pox, which showed a marked indication of decline at the date of the last annual report, had in the course of the year just ended entirely ceased. In September last only two patients were admitted into the hospital; and during a part of November the hospital was entirely empty. Of the 189 cases admitted during the year, 179 had been vaccinated. The general mortality had been 24·3 per cent.—21 per cent. on the vaccinated, and 77 per cent. on the non-vaccinated cases.

His Excellency the Viceroy of India recently laid the foundation stone of a native hospital at Calcutta.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this request.

All communications intended for insertion must bear the name and address of the writer; not necessarily for publication, but as a voucher of good faith.

Subscriptions in the United States.—A correspondent has drawn our attention to the fact, that some of the houses in the United States are charging the enormous figure of 15 dollars per annum (more than [illegible]) for supplying this Journal to different parts of the States. We beg, therefore, to state that we shall be happy to supply the same regularly, post free, per annum, if paid in advance, for considerably less than half this amount, viz., six and-a-half dollars (about £1 6s. 0d.), either direct from our offices in this country, or through our recognised agents in the United States.

Law respecting Periodicals, Newspapers, &c.—1. Subscribers who do not give express notice to the contrary, are considered as wishing to continue their subscriptions. 2. If Subscribers order the discontinuance of their periodicals or newspapers, the publisher or publishers may continue to send them until all arrears are paid up, and Subscribers are held responsible for all numbers sent. 3. If Subscribers neglect or refuse to take the periodicals or newspapers from the office to which they are directed, they are held responsible till they have settled their bills. Sending numbers back, or leaving them in the office, is not such notice of discontinuance as the law requires. 4. If Subscribers remove to other places without informing the publisher, and their periodicals or newspapers are sent to the former directions, they are held responsible.

Dr. J. S., Manchester.—The gentleman named has taken both Medical and Clerical degrees. He has recently given up medicine and gone into the church; you will find the curacy he occupies on reference to the official "Clergy List," published by Baillière, Tindall, and Cox.

A Lucrative Appointment.—The Public Health Act of 1872, which came into operation in November last, opens a valuable field to the Profession, and at the same time gives an impetus to the study of Analytical Chemistry, Public Hygiene, and Sanitary matters generally. There are now about a dozen appointments in different parts of the kingdom for competition, the most valuable—from a pecuniary point of view—being that announced in our advertising columns for the county of Oxford, the emolument attached to which is £760 per annum. One or two others of less importance will be found under the head of "Vacancies."

Economy in Coals.—A correspondent has thrown out a suggestion to which we are glad to give publicity. He states that in view of the enormous increase in the price of coals, he has had a thick sheet of iron fixed at the bottom of the grates; the fire, lighted from the top, burns slowly downwards, until it reaches the plate, which becomes red hot and throws out a great heat, whilst the draught being stopped, the coals burn away much more slowly, and the heat is retained for a longer space of time than with the ordinary grates. The plan suggested by our correspondent is not new, as we have seen it in the consulting room of more than one practitioner, but it is one which should be more widely known and adopted, especially in hospitals and dispensaries, where the item for coals is at all times a serious one in the year's balance sheet, and will be doubly so at the present almost prohibited prices.

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

Notes on Asthma. Second Edition. By J. C. Thorowgood, M.D. London: J. and A. Churchill.

The Pathology and Treatment of Club Foot. Second Edition. By W. Adams, F.R.C.S. London: J. and A. Churchill.

Lessons in Elementary Anatomy. By St. George Mivart, F.R.S. London: Macmillan and Co.

A Tract for the Times. By John R. Adams.

Boston Medical Journal. La Gazette Médicale. American Journal of the Medical Sciences. Annales d'Occulistique. Monthly Microscopical Journal. Chicago Medical Examiner. Allegemeine Weiner Medizinische Zeitung. Indian Medical Gazette. Gazette Médicale Belge. The Practitioner. The Students' Journal.

APPOINTMENTS.

Cronyn, J., L.K.Q.C.P.I., F.R.C.S.I., Assistant Lecturer on Midwifery at the Royal College of Surgeons, Ireland in consequence of Dr. Sawyer's illness.

Fraser, J., M.B., C.M., Medical Superintendent of the Fife and Kinross District Asylum.

Gregory, G., L.R.C.P.L., M.R.C.S.E., Medical Officer of Health for the Bolton Rural Sanitary District.

Grigg, W. C., M.D., M.R.C.P.L., a Medical Officer for In-patients, Queen Charlotte's Lying-in Hospital, St. Marylebone Road.

Harris, G. S. D., L.R.C.P.L., Medical Officer of Health for the Leighton Buzzard Rural Sanitary District.

Kirby, Mr. A. E., Assistant Medical Officer to the General Infirmary Leeds.

Maybury, H. M., M.D., C.M., M.R.C.S.E., Resident Medical Officer to the Islington Dispensary.

Meadows, H., M.B., C.M., Medical Officer to the Leicester Provident Dispensary.

Moxon, W., M.D., a Physician to Guy's Hospital.

Muriel, G. J., M.R.C.S.E., Surgeon to the Whitehaven Infirmary.

Parnell, G. C., M.R.C.S.E., House-Surgeon to the Worcester General Infirmary.

Phillips, J. M., M.D., Medical Officer of Health for the Urban Sanitary District, Aberavon.

Pollock, R., L.R.C.P., Medical Officer of Health for the Acton District.

Roberts, E., L.R.C.P.Ed., Medical Superintendent to the Infirmary for Epilepsy and Paralysis, Portland Place, Regent's Park.

Seaton, E., M.D., M.R.C.S.E., Medical Officer of Health for the Urban Sanitary District of the Borough of Nottingham.

Stephens, T., M.R.C.S., Public Vaccinator to the Tynemouth Union.

Taylor, F., M.D., M.R.C.P., Assistant-Physician to Guy's Hospital.

VACANCIES.

County of Oxford. Medical Officer of Health, under the Sanitary Act, 1872. The salary attached is £750 per annum. Candidates must address C. E. Thornhills, Esq., Woodleys, Woodstock, Oxon, on or before the 20th instant.

Borough of Bradford. Medical Officer of Health. Salary £500 per annum. Conditions the same as Taunton.

Halifax Infirmary, Yorkshire. House Surgeon. Salary increasing from £80, with board and residence. Applications to Dr. Alexander, Halifax.

Dundee Royal Infirmary. Medical Superintendent. Salary £200 per annum, with board and residence. Medical Assistant is also required at the same Institution, at a salary of £50, with board.

York Royal Sanitary Authority. Medical Officer of Health. Salary £200 per annum. Applications to H. Breary, Esq., York, before the 28th instant.

Devon Hospital, Buxton. House-Surgeon. Salary £100 per annum, with board and residence. Address Mr. J. Taylor, at the Hospital.

Banbury Union. Medical Officer. Salary £125, to include all extras. Applications to be addressed to the Clerk of the Guardians.

Rotherham Union. Medical Officer of Health, at a salary of £600 per annum. The duties will be those contained in the order of the Local Government Board. Applications to J. Barras, Esq., Rotherham.

Ely Union. Medical Officer of Health. Salary £150. Duties as per Sanitary Act. Applications to G. S. Claxton, Esq., Ely.

Brighton and Hove Dispensary. House-Surgeon. Salary £100 per annum, with residence.

West London Hospital. Dispenser. Applications to the Secretary.

Teignmouth Infirmary. House-Surgeon. Salary £50, with board.

Nottingham General Hospital. House-Surgeon. Salary £80, with board.

MEETINGS OF THE LONDON SOCIETIES.

Wednesday, February 12.

Royal College of Surgeons of England, 4 p.m.—Professor Erasmus Wilson, "On Dermatology."

Epidemiological Society, 8 p.m.—Dr. Wm. Squire, "On the Periods of Infection in Epidemic Disease."

Friday, February 14.

Royal College of Surgeons of England. 4 p.m.—Hunterian Oration, by Mr. Henry Hancock.

Clinical Society of London, 8½ p.m.—The President's Address.—Mr. Arnott will exhibit a Patient on whom a Soft Cancer in the Parotid Region has been treated by Caustics; no return of the Disease after four years.—Mr. Thornton will relate "Two Cases of Thyrctomy for the Removal of Growths from the Larynx."—Dr. Morell-Mackenzie, "On the Results of Thyrotomy for the Removal of Growths from the Larynx."

Saturday, February 15.

Royal Institution of Great Britain, 3 p.m.—Dr. Edward A. Freeman, "On Comparative Politics."

Monday, February 17.

Medical Society, 8 p.m.—Ordinary Meeting.

Tuesday, February 18.

Pathological, 8 p.m.—Ordinary Meeting.

Royal Institution, 3 p.m.—Professor Rutherford "On the Forces and Motions of the Human Body."

◆

OPERATION DAYS AT THE LONDON HOSPITALS.

Wednesday, February 12.

Middlesex Hospital.—Operations, 1 p.m.
Royal Westminster Ophthalmic Hospital.—Operations, 1½ p.m.
St. Bartholomew's Hospital.—Operations, 1½ p.m.
St. Thomas's Hospital.—Operations, 2 p.m.
St. Mary's Hospital.—Operations, 1¼ p.m.
King's College Hospital.—Operations, 2 p.m.

COUNTY OF OXFORD.—MEDICAL OFFICER OF HEALTH.—See the Public Health Act, 1872, and Orders of the Local Government Board.—A Committee, acting on behalf of the Rural and Urban Sanitary Authorities mentioned in the Schedule, are desirous of selecting a Medical Officer of Health for the whole area within the jurisdiction of such Authorities for three years.

The Officer will be required to reside in Oxford, and to devote his whole time to the duties of his office.

The selection will be provisional until the same shall be confirmed by the several Authorities and by the Local Government Board.

The salary will be £760 per annum, to be paid rateably by the several Authorities, and no further allowance will be made for travelling expenses, but, if one or more of the Authorities shall refuse to confirm the selection made by the Committee, the salary of the Officer will be diminished to the extent of the contribution of the Authority or Authorities so refusing.

Candidates for the office are requested to address their applications, stating age and legal qualification, together with such testimonials as they may desire to submit, to C. E. Thornhill, Esq., Woodleys, Woodstock, Oxon, so that the same may be received on or before the 20th inst.

February 6th, 1873.

Royal College of Surgeons, Dublin,
12th day of Feb., 1873.

SLIGO UNION—SLIGO DISPENSARY.

THE BOARD OF GUARDIANS having fixed the Salary of Apothecary at £80 per annum, the Dispensary Committee will proceed to elect a qualified APOTHECARY, on the 14th day of February, at 12 o'clock, at the above-named Salary. Candidates are required to produce their Testimonials on the day of Election. Personal attendance desirable.

DANIEL MACGILL, Hon. Sec.

31st January, 1873.

APOTHECARY ESTABLISHMENT FOR SALE.

TO be SOLD by PRIVATE CONTRACT, the INTEREST of the REPRESENTATIVES of the late H. P. Smith, Esq., L.A.H., in that Shop and Premises in the main street of the town of Strabane, in which the business of an apothecary has been successfully and extensively carried on for a great many years. The business has been conducted since the death of Mr. Smith by his Representative, and is at present in a flourishing condition. The receipts and sales of the business for several years past have averaged a sum exceeding £600 each year.

This is the only apothecary establishment in Strabane, a town of 5,000 inhabitants, 18 miles distant from Derry, and surrounded by a populous and rich district of country.

The stock of medicines at present on hand is large, and the shop fixtures are excellent, being almost as good as new.

The premises are held by lease for 30 years from the 1st November, 1866.

Proposals by intending purchasers will be received by the undersigned up to the 1st of March next.

Strabane, 28th Jan., 1873. THOMAS LYLE, J.P.

THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.

Patron:—H.R.H. THE PRINCE OF WALES.

This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develope the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £25 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote.

Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c., can be had at the office,

40 MOLESWORTH STREET, DUBLIN,
W. O'NEILL, Secretary.

Irish Poor-Law Intelligence;

UNDER AUTHORITY OF THE

IRISH MEDICAL ASSOCIATION.

WATERFORD PETTY SESSIONS.

Mr. Mackey said he wished to direct the attention of their worships to the fact that the medical practitioners of Waterford exhibited great neglect in the discharge of their duty in connection with cases of vaccination. It was true they usually furnished certificates of vaccination to the parents of the children, but they almost uniformly neglected to supply the registrars with duplicates of such certificates, an omission which necessarily led to much inconvenience and trouble.

Their Worships were of opinion that it would only be necessary to have the complaint go before the public as stated by Mr. Mackey, and they were sure the Medical gentlemen would pay more attention to the matter in future.

MULLINGAR UNION.

The Clerk read the following notice of motion :—" To take into consideration the amount of superannuation allowance to be granted to Dr. North, Medical attendant of the Tyrrellspass Dispensary District, who has resigned in consequence of ill health."

Mr. Hornidge moved that Dr. North be allowed two-thirds of his salary, which would amount to £70 a year.

Mr. Hornidge said that Dr. North had held the situation for about seven years and a half.

Mr. Hevey said that he had to resign his situation from ill health, and he was afraid they would not be long paying him his superannuation allowance.

Dr. Burke remarked that he was always most anxious to support the Medical officers of diipensary districts, but he was certain the Local Government Board would not sanction the full amount of superannuation as proposed, in consequence of his short service; he would suggest that a reasonable amount, consistent with his length of service, be recommended.

Mr. Fetherstonhaugh proposed that £50 a year be allowed Dr. North as superannuation.

After some conversation on the subject, two resolutions were submitted, one for £45 per annum, the other for £40.

The Board divided, when there appeared—for £45 per annum, 6; for £40, 9.

It was then agreed that Dr. North be allowed £40 per annum superannuation, subject to the approval of the Local Government Board.

NENAGH GUARDIANS.

There was a claim from Dr. Cashel for two guineas, while acting as *pro tem.* for Dr Cahalan, by orders of the Nenagh Dispensary Committee.

The Clerk remarked that this bill had been disapproved of by the Board of Guardians on a former occasion.

Mr. H. H. Poe thought the Guardians acted contrary to both law and equity in refusing Dr. Cashel the two guineas. Dr. Cahalan was not absent at the time on his own business; he was acting under a command, which could not be disobeyed by the highest man in the land. He had been subpœnaed, and if he did not go where it required, he would refuse at his peril. The committee appointed Dr. Cashel to act in Dr. Cahalan's place while he would be at Clonmel.

Mr. Head—If Dr. Cahalan went there, he got his viaticum, and the gentleman that wanted him ought to pay. Dr. Kittson, of course, included it in his costs.

Mr. H. H. Poe—Supposing he went, as he had a right to do, and did not leave anyone in his stead, the Committee should appoint a doctor.

Mr. Head—Dr. Cashel can make those who appointed him pay him. At all events, the Guardians cannot now order him payment without rescinding the resolution on the books, which would require a fortnight's notice.

Mr. Martin Ryan—It is a great hardship to be thus putting additional rates on the people. Dr. Cahalan was neither sick nor on the business of the Union, and therefore, the man in his place has no right to be paid out of the rates.

Mr. Poe—Dr. Cashel has a right to be paid by somebody. The Committee appointed him, and should see him paid.

It was remarked that the Dispensary Committee gave Dr. Cashel an order for payment but the Guardians had nullified the order.

The subject here dropped.

WEEKLY RETURN OF BIRTHS AND DEATHS IN DUBLIN AND THE SUBURBAN DISTRICTS.

The deaths registered in the Dublin district represent an annual mortality of 27 in every 1,000. In London the death rate was 21, in Glasgow 29, and in Edinburgh 20.

The births amounted to 217, the average being 176.

The deaths were 164, the average was 205. It should be stated that, according to the returns received, only one of those which have occurred in the South Dublin Union Workhouse during the last fortnight has been registered.

Nine deaths from fever were registered during the week. Of these 1 was reported as having occurred from typhus, 6 from typhoid, and 2 from simple continued fever.

Scarlet fever caused 6 deaths, measles 3, whooping-cough 6, and croup 4.

Fourteen children died from convulsions.

Twenty-three deaths were ascribed to bronchitis, and 4 to pneumonia. In the corresponding week of the year 1867 the number of deaths registered from bronchitis amounted to 102. Three deaths were ascribed to apoplexy.

Heart disease was the cause of 10 deaths, and aneurism of 2.

Twenty-two persons fell victims to phthisis, 1 to mesenteric disease, 4 to hydrocephalus, and 2 to scrofula.

CAVAN UNION.

THE Clerk read the minutes of proceedings of the different Dispensary Committees in the Union, specially convened to consider the Doctors' application for increase of salary. Arva, Ballyhaise, and Stradone refused to recommend the increase; Cavan, Ballynagh, Belturbet, Killeshandra, and Kilnaleck recommended it.

It was moved that each case be considered separately, and subsequently moved as an amendment that they be taken in the aggregate. A poll was taken, and the amendment carried by a majority of 16.

Mr. Babington moved that 20 per cent. be added to each Doctor's salary, that is what the Cavan Committee recommended Dr. Malcomson to get.

Mr. Boylan was opposed to any increase and would make an amedment to that effect.

Mr. Thomas Reilly said Dispensary Doctors (except one) had only £85. Last year they had on an average 215 red tickets each—and on an average each ticket represented about 4 visits—they had to attend twice a week at the Dispensary. If they allowed 6d for each visit and 10s a day for attending at the dispensary it would amount to about £115 a year. The workhouse Doctor had in the year 1871, 1,068 patients under his care without taking into account the patients in the infirm ward. He had to visit them daily and write down prescriptions for them, for which he received only £100 a year, while the doctor of another institution in the county who has not more than twenty patients a-day under his care is paid £540 a year. If the increase be granted, the Government will pay one half of it, and the Union the other. As the landlords will pay half again, very little of it will come off the tenant farmers.

Mr. Knipe—The doctors are not half paid.

Mr. Reilly—I know an instance at present, where a doctor is attending on one ticket seven members of a family ill with fever.

Mr. Telfer—If they think they are not paid enough let them resign.

A poll was then taken, when there voted—for Mr. Babington's motion, 11; for the amendment, 51.

Major Phillips was about giving notice of motion to consider each case separately, when it was agreed to let the matter drop until after the election of the new Board.

CAVAN UNION.

THE Chairman read the following letter from the Local Government Board:—

"Local Government Board, Dublin,
3rd February, 1873.

"SIR,—The Local Government Board for Ireland acknowledge the receipt of minutes of proceedings of the Board of Guardians of Cavan Union on the 21st ultimo, containing a resolution relating to the application of the workhouse and dispensary Medical officers for an increase in their salaries, in which the guardians propose that no increase be granted; and in reference thereto, the board forward herewith, for the consideration of the guardians a communication which they have received from the Medical officers of the union on the subject.

"The board have at the same time to inform the guardians, that the salaries of all the dispensary Medical officers in the union are considerably below the average salary of the dispensary Medical officers in Ireland, and they recommend the guardians to re-consider their resolution on the subject.

"You are requested to return the enclosed letter to this office.

"By order of the board,
"B. BANKS."

"To the Clerk of Cavan Union."

(Enclosure referred to.)

"To the Local Government Board.

"GENTLEMEN,—We have the honour herewith to enclose a copy of a memorial which we, Medical Officers of the Cavan Union, presented to the Cavan Board of Guardians, asking for an increase to our present inadequate salaries, as our memorial sheweth.

"This memorial having come before the guardians on the 3rd ult., they referred the matter in the first instance for consideration to each dispensary committee. Five committees, namely:—Cavan, Belturbet, Killeshandra, Ballinagh, and Kilnalech, reported in favour of an increase.

"The question again came before a special meeting of the board on this day, when our application was refused.

"We now beg to submit our claim to your board for consideration, praying that you will be pleased to request the board of guardians to reconsider the matter with a view to comply with the request of the memorial generally, or that each Medical officer's case be considered on its own merits.

"We have the honour to remain, your most obedient servants, W. Malcomson, H. W. Thomson, M. Moore, H. Alcock, Charles Jackson, J. Mathews, Thos. S. O'Reilly, R. Y. Kenny."

The Chairman suggested that it be re-considered at an early meeting of the new board.

Mr. Thompson said it had been negatived by a large majority, and agreed with the Chairman.

Mr. Hewitt—The present board would vote the same way again, better wait until after the elections.

On the motion of Mr. Thompson, seconded by Mr. Kennedy, the re-consideration of the subject was postponed until Tuesday, the 1st of April.

YEARLY SUMMARY OF THE WEEKLY RETURNS OF BIRTHS AND DEATHS IN DUBLIN AND THE SUBURBAN DISTRICTS.

Births.—During the year 1872 there were registered in the Dublin District, 8,449 births, being equal to a ratio of 27 per 1,000 of the population, 31 in every 1,000 north of the river Liffey, and south of the river 26 per 1,000. In the suburban districts the number of births registered amounted to 1,504, or 23 in every 1,000. In London the births registered were 117,200, being equal to a rate of 35 in every 1,000; in Glasgow the number was 41 per 1,000; and in Edinburgh it was 32 per 1,000.

Deaths.—8,973 deaths were registered in the Dublin District, being equal to a ratio of 1 in 35, or 29 in every 1,000. On both sides of the river there were an equal ratio of 31 in every 1,000. In the suburban districts the deaths amounted to only 19 in every 1,000 of the population. The deaths in Belfast during the year afford a ratio of 24 in every 1,000; in Cork 33 per 1,000; in Limerick it was 22, in Londonderry 19, in Waterford 24, in Galway 23, and in Sligo 18. In London during the year 1872, 21; in Glasgow, 28; and in Edinburgh, 26.

Diseases.—There were 2,622 deaths from zymotic diseases, this number amounting to 29 per cent. of the total deaths. The average for the preceding eight years, including those from cholera during 1866, was 1,817. This increase is due to the small-pox, which caused 1,350, or more than one-half, of the deaths. The deaths from small-pox form 15 per cent. of the deaths from all causes, and are equal to a mortality of 4·3 in every 1,000 persons living. 581 were registered in the first quarter, 582 in the second, 155 in the third, and 32 in the fourth. In 1871, 207 deaths from small-pox were registered. *There was not one death from this disease registered in the Dublin District during the year* 1870. 204 deaths from small-pox were registered in Belfast, and 871 in Cork, the mortality in the latter district being equal to 9·6 in every 1,000. In the Dublin District measles caused 202 deaths during the year 1872, against 26 in the preceding year, and diphtheria 26, or 4 more than in 1871. Constitutional diseases caused 1,756 deaths, or 19·57 per cent. of the total. Of these, 1,086, or 12 per cent. of the total deaths resulted from phthisis, 103 over the average eight years; 172 from hydrocephalus; 146 from mesenteric disease; 66 from scrofula; 150 from cancer. Bronchitis proved fatal in 1,076 instances, or 12 per cent. of the total deaths, and 160 deaths were ascribed to pneumonia.

LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTH OF JANUARY, 1873.

3rd.—Brown, Samuel, 19 College Square East, Belfast, M.D., 1872, and M. Ch., 1872, Q.U.I.

3rd.—Hamilton, Stewart, Sandymount, Co. Dublin, Lic. R. Coll. Surg. Irel., 1871, Lic. K. Q. C. Phys. Irel., 1872.

3rd.—Johnstone, Chas. Alex., Balbriggan, Co. Dublin, Lic., 1869, and Lic. Midwfy., 1869, R. Coll. Surg. Irel., Lic. K. Q. C. Phys. Irel., 1872.

21st.—Graham, James, Aughnacloy, Co. Tyrone, M.D., 1872, and M. Ch., 1872, Qu. Univ. Irel.

22nd.—Brady, Andrew John, Clonturke, Kinawley, Co. Fermanagh, Lic., 1873, and Lic., 1873, K. Q. C. Phys. Irel., Lic. R. Col. Surg. Irel., 1872.

22nd.—Luther, Edward Wentworth, 28 Upper Leeson St., Dublin, Lic. R. Coll. Surg. Irel., 1872, Lic., 1872, and Lic. Midwfy., 1872, K. Q. Coll. Phys. Irel.

22nd.—Webb, Samuel Henry, 6 Charlemont Mall, Dublin, Lic. R. Coll. Surg. Irel., 1872, Lic., 1873, and Lic. Midwfy., 1873, K. Q. C. Phys. Irel.

22nd.—Mallins, Henry, Grosvenor House, Rathgar, Co. Dublin, M.B., 1872, and M. Ch., 1872, Univ. of Dub.

22nd.—Sutton, John Richard Henry, 22 Harcourt Street, Dublin, Lic. R. Coll. Surg. Irel., 1872, Lic., 1873, and Lic. Midwfy., 1873, K. Q. C. Phys. Irel.

27th.—Anderson, Richard John, Newry, Co. Down, M.D. Qu. Univ. Irel., 1872, Memb., 1872, and Lic. Midwfy., 1872, R. Coll. Surg. Eng.

28th.—Roe, Robert George, Newport, Co. Mayo, Lic. R. Col. Phys. Edin., 1872, Lic. R. Coll. Surg. Edin., 1872.

28th,—Lucas, Edmond Allen, Killummery Glebe, Dromahaire, Co. Leitrim, Lic., 1871, and Lic. Midwfy., 1871, K. Q. C. Phys. Irel., Lic. R. Col. Surg. Irel., 1871.

29th.—Bowers, Edward, Graguevine, Piltown, Co. Kilkenny, Lic., 1872, and Lic. Midfy., 1873, R. Coll. Surg. Irel., Lic. K. Q. C. Phys. Irel., 1873.

30th.—Whitla, James, Monaghan, Lic. Apoth. Hall Dub., 1866.

30th.—Barry, Francis, Coolamaine, Oylgate, Co. Wexford, Lic. R. Coll. Phys. Edin., 1872, Lic. R. Coll. Surg. Edin., 1872.

31st.—Gubbins, William Launcelot, 18 Trinity College, Dublin, M.B., 1872, and M. Ch., 1872, Univ. Dub.

ERGOT OF RYE.

In a discussion at the Academy of Medicine, Dec. 17, 1872, Dr. Devilliers maintained that *sages femmes* such as are educated at the best French schools, do not understand how to use ergot of rye, and that they should be forced by law to limit the use of it to *post partum* hæmorrhage alone, and only be allowed to obtain it on presenting an order for it from a Medical man. Dr. Depaul, on the other hand, demands a more extended education for midwives since custom concedes to them the employment of ergot of rye, and many of them even make use of the forceps. Leave them the ergot, says Depaul, but teach them how to use it. Dr. Guérin observed that if ergot of rye has its inconveniences, it has also its incontestable utility, for it brings on the flow of the lochia and often prevents the accidents of puerperal fever.—*The Doctor.*

A CAUSE OF STRICTURE OF THE URETHRA.

We are aware that death has occurred as a consequence of cauterisation of the prostatic urethra, and we hav often wondered that less serious effects do not sometimes follow; our doubts are set at rest by a communication of Mr. C. O. Aspray to the *Medical Press and Circular* (Dec. 18, 1872). The author has clearly traced stricture to this cause. We do not mean to assert that cauterisation of the urethra is never necessary, but we think it a sin and a shame to cauterise a healthy young man who might be cured by marriage. We judge from experience that the rage for this treatment caused it to be applied much too frequently, and, to use Mr. Aspray's expression, unnecessarily.—*The Doctor.*

ELIMINATION OF ALCOHOL.

Dr. Dupre has renewed some experiments on this subject and concludes—

1st.—The quantity of alcohol eliminated daily does not increase with the continued injestion of alcohol.

2nd.—The elimination of alcohol, after the injestion of one or more doses, ceases from the ninth to the twenty-fourth day after the injestion of the last dose.

3rd.—The quantity of alcohol eliminated by the kidneys and lungs is but a very small part of that injested.

In the course of his experiments the author found that after six weeks of total deprivation from alcoholic drinks, and even in one individual who completely abstained from alcohol, that the urine contains sometimes a substance which is not alcohol, but which presents the characters by which we generally recognise alcohol. This body passes over among the earliest products of distillation, gives acetic acid on being oxydised, reduces the bichromate of potash when dilute sulphuric acid is present, and its aqueous solution has a lower density than water. It furnishes iodoform, and exists in the urine in a very small quantity.—*The Doctor.*

◆

DILATATION IN STRICTURE OF THE RECTUM.

The *Mouvement Medicale* reports a case of stricture of the rectum, treated by dilatation, which resulted in general peritonitis and death. M. L. Thaon, related the case before the Société Anatomique. The patient was a woman, æt. 28. In 1872, she entered the Lariboisiere Hospital. No syphilis, dysentery of twelve years' standing. Two years previously, a rectal stricture had been diagnosed about three inches from the anus, which would not admit the pulp of the index finger. When she came under the care of M. Thaon, she could only get her bowels moved by the aid of purgatives, and after using a No. 16 bougie. She was suffering from colic, and ill-nourished. It was determined to employ progressive dilatation. For this purpose, one of Mathien's dilators was inserted, meeting no obstacle until about 15 centimetres of it had entered. Here an obstacle was felt, but overcome without difficulty, and the instrument was pushed forward, but immediately the patient was seized with a severe pain in the left fossa iliac; which spread over the whole abdomen, and rigors ensued. The next and following days symptoms of general peritonitis, hiccough, vomiting, small and rapid pulse, meteorism, contracted features; death six days after the operation. At the autopsy, all the abdominal organs were found covered with soft, purulent, false membrane; the intestine was adherent to the abdominal walls; greyish pus was collected in the cavity of the true pelvis; old lamellated adhesions bound the post-surface of the uterus to the rectum. The following lesions were found at the lower extremity of the large intestine. About 9 centimetres above the anus, was the most contracted portion; at this spot the rectum measured transversely 22 millimetres (about 10 lines). The stricture was formed of a circular diaphragm, projecting, almost linear. Above and below this part, the rectum was contracted and ulcerated, upwards for 8 centimetres, downwards to the anus. The ulceration above the stricture, which was limited by a distinct margin, had destroyed the mucous membrane. Above the upper limit of the diseased parts there was an ulcerated spot, the tissues being about 1½ millimetres thick, and strong enough to resist considerable pressure with a blunt instrument. No escape of feculent matter into the peritoneal cavity could be detected. The stricture was pronounced to be the result of simple fibrous hypertrophy, and of cicatricial contraction arising from dysentery. The acute peritonitis was attributed to the breaking down of adhesions by the bougie.

Mr. Thomas Smith has been appointed surgeon to St. Bartholomew's Hospital, in the vacancy caused by the death of Mr. Coote. Mr. Howard Marsh will probably be appointed assistant-surgeon in Mr. Smith's place.

ACCIDENTS IN FLAP EXTRACTION OF CATARACT, AND THE METHODS OF AVOIDING THEM (a).

By Archibald Hamilton Jacob, M.D.Dub., F.R.C.S.,

Chief Surgeon to the Dublin Eye and Ear Infirmary, Ex-Ophthalmic Surgeon to the City of Dublin Hospital.

In the following communication I have two objects in view. The first of these is to call attention to some minor details in connexion with the operation of flap extraction of cataract, which, although they may appear to be insignificant in themselves, and hardly worthy of special notice, I have been taught by experience are of actual importance, and exercise a decided influence on the success of the result. My second object is to draw such a comparison as my experience enables me, between the results of the original old operation of Daviel, and of the numerous recent modifications of it, of which many high authorities have spoken so favourably. I may thus, perhaps, succeed in showing that by a careful and punctilious attention to a variety of minor details, the operation of flap extraction may be made as satisfactory in the performance, and much more satisfactory to the patient than any of the fashionable methods to which I have referred.

The operation of flap extraction has, ever since its invention by Daviel a century and a quarter ago, been recognised as one attended with much risk of accident, and requiring considerable adroitness on the part of the operator, and at the present day it would seem, even by operators of known ability, to be usually relegated to ophthalmic specialists. The very latest surgical work, the fifth edition of the work of Professor Gross, of Philadelphia, says of flap extraction—"It requires great coolness and dexterity on the part of the surgeon for its successful execution. It is said of Wenzel that he spoiled a whole hatful of eyes before he had learned the art of extracting. This statement, without being strictly true, affords an excellent illustration of the difficulties which attend the operation, and a reason why so few practitioners are found who are ready and willing to undertake it." All operations for the removal of cataract, either by absorption or by linear extraction, accompanied by iridectomy, have had their origin in the dangers of the original procedure, and the arguments employed by the author of each of the multitudinous new methods of operation are usually grounded upon the excessive proportion of failures which attend upon flap extraction.

It will be acknowledged that, in theory at least, the original method of extraction is more perfect than any of those which have been intended to supplant it, inasmuch as it involves, if perfectly successful, no other mutilation of the eye than the removal of the opaque lens. In a perfect case, of which I have seen many, the vision obtained by the adaptation of cataract glasses is as perfect as if cataract had never existed, no personal deformity whatever is present, and the structures of the eye run no risk whatever of injurious after-consequences. Every other extraction operation, with the exception of that of Mr. Macnamara, of Calcutta, and that of M. Liebrich, a procedure recently invented by Mr. Warlomont of Brussels, involves the excision of a part of the iris, and the objections to this process are acknowledged by all those who have inculcated the proceeding, it being defended, however, on the ground that the chances of success are greatly enhanced by it. If it could be shown that the risk of flap extraction might, by the adoption of certain precautions, be reduced to the limit which has been claimed for other operations, I believe every one would prefer it, and the unscientific, and unsurgical mutilation which is now considered necessary, would be no longer thought of.

In the selection of a case for extraction, the point on which I would particularly dwell is, that we should be quite certain that the solidification of the lens is complete in all its parts. This is a precaution which, perhaps, does not receive as much attention as it deserves. When an operation has been once decided on, the patient, especially if he is a business man, is usually anxious to have it over, and the surgeon may be himself disposed to close the matter at once. I think it is of great importance that this temptation should not be yielded to, for I have found that as a rule a case in which any part of the cortex has been soft and immature, has turned out to be troublesome in the operation, and not satisfactory in its result. The leaving of scraps of cortical cataract in the anterior chamber, is, I believe, one of the most fertile causes of secondary iritis, and I have seen cases in which failure of union in the flap has been attributable to such cases. Moreover, in the case of an immature lens, abundant fragments frequently remain in the capsule after the escape of the body of the lens, and becoming opaque, give rise to secondary cataract.

(a) Read before the Surgical Society of Ireland.

It is easy to make sure that no such fragments occupy the pupil, but hardly possible to detect them when hidden in the angles of the anterior chamber, where they will be likely to do much greater mischief. All authors advise such fragments to be removed with the scoop; but although I concur in the necessity of doing so when they can be found, I object very much to the introduction of an instrument into the eyeball at the risk of bruising the iris, and disturbing the vitreous, if such procedure could be avoided. I, therefore, never attempt an extraction until I have fully dilated the pupil, and satisfied myself as far as possible that the circumference of the lens is thoroughly opaque, and I rarely fail to find the pupil quite black and clear when I make my examination previous to closing up the eye after operation.

I always operate on the left eye from the front of the patient, and I do not believe in an adroit incision being made with the left hand except perhaps by a left-handed person. Mr. Wolfe, of the Aberdeen Infirmary, says he always operates so, and it has been the boast of some operators that the vastness of their manipulative experience has enabled then to acquire a marvellous sleight of hand for this purpose. I confess that I do not find it too easy to make a flap of the exactly correct size, in the exactly correct place, without injuring the iris, and I should be very sorry to risk my patient's eye for the sake of displaying my cleverness in manipulation. On this point Mr. Haynes Walton says—"It is notorious that extraction in the left eye is much more frequently attended by failure than in the right, and the occurrence is, of course, attributable to the greater difficulty offered by the position of the eye." Excepting the temptation to an operator to display manual dexterity, I know of no reason for such failure in left eye extractions, nor do I think that there is any "difficulty offered by the position of the eye." If the patient be placed lying quite close to the side of the table, I think the operation from the front will be found as convenient as that from behind.

I have recently stated at the Surgical Society that, until I have occasion to change my mind, I shall never attempt a capital eye operation without the use of ether, and I repeat here that I do not think any operator will in future be justified in attempting to extract without its help.

The older writers on ophthalmic surgery, including Mackenzie and Lawrence, give minute directions for the steadying of the eye by the fingers, and the method which is now usual of fixing the globe with a forceps is not mentioned by them. On the other hand, some of the writers of the present day, including Stellwag von Carrion and Soelberg Wells, mention fixation with the forceps as an operator. The old method of fixing the eye-ball and raising the lids is illustrated in the accompanying figure (1). Although I think that it cannot be depended on for fixation of the eye-ball during a procedure so delicate as the making of a flap section, in which complete stability is essential, I think it ought to be retained as the means for steadying the eye in other procedures, such as needle operations and removal of foreign bodies. I consider perfect stability of the eye and the alternative which may be dispensed with by the skilful maintenance of a pressure to counterbalance the force necessary for puncturing the cornea, are essential to the making of a good flap, and as I know of no efficient means of obtaining such a condition, except the fixation forceps, I always use it to steady the eye. Mr. Soelberg Wells says:—"The chief difficulty of operating without fixation is that the eye may roll swiftly inwards directly the puncture is made, or even before, so that the cornea becomes almost hidden in the inner canthus, and the knife has to traverse the anterior chamber and make the counter-puncture, without the operator being able to see its course. This will prove extremely embarrassing to the beginner, and may even unnerve him for the remainder of the operation." This opinion perfectly coincides with my own experience, and having at first always operated by steadying the eyeball with my fingers, I now never attempt to do so without fixing it firmly with the forceps. I confess I do not like the idea of lacerating the conjunctiva however slightly, as this method cannot fail to do, but I cannot say that I have ever seen any subsequent ill result from the practice, and if I did I should, nevertheless, consider that the advantage of immovability of the eyeball during the operation, would abundantly repay the risk.

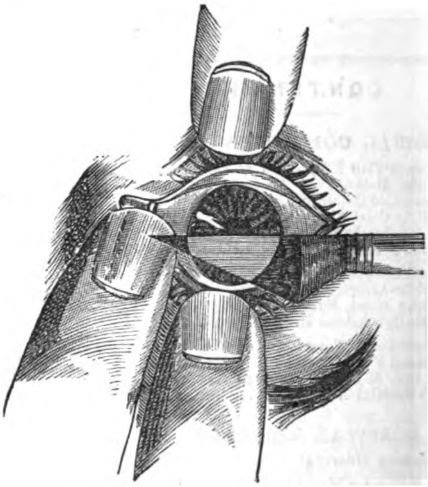

FIG. 1.

OPERATION ON RIGHT EYE, FROM THE FRONT, WITH RIGHT HAND.

The ordinary fixation forceps I have found very ineffective. Its bite is very minute and very sharp, and it is liable to tear away from its hold on the conjunctiva just at the moment when its services are most wanted, I have, therefore, obtained from Paris a forceps—of which the points of seizure are depicted in Fig. 2—which takes a wider and more effective grip, and inflicts upon the conjunctiva, no injury of more moment than a contusion. Mr. Soelberg Wells, Mr. France, of Guy's hospital, and others, direct the eye to be seized a little below or above the cornea, according as the section is to be made above or below. Mr. Macnamara, on the other hand, advises the hold to be taken close to the equator of the eye, and internal to the cornea, I think the latter method of fixation is much the best, for I have found that if the hold be taken below or above, the position of the operator's hands is awkward, and the eye rotates more or less on its axis when the pressure of the puncturing knife is applied to it. My own rule is to seize the conjunctiva immediately above the spot where I mean to make the counter-puncture, and thus I

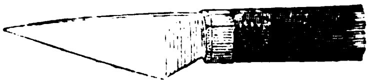

FIG. 2.

not only keep my left hand out of the way, but I have my fixed point directly opposite to the point of entry of my knife, and the exact place for my counter-puncture is marked for me.

(To be continued.)

◆

CLINICAL REMARKS ON THE SUPPOSED VALUE OF STRYCHNIA IN ATROPHY OF THE OPTIC NERVE.

By Jabez Hogg,
Surgeon to the Royal Westminster Ophthalmic Hospital, &c.

(*Continued from page* 42.)

The cases given are taken from my note-book without reference to any particular order, and simply because they happen to represent in a well-marked manner, the typical kind of case most frequently ending in white-atrophy. I will not unnecessarily occupy time by giving the history of other cases arising out of similar, cerebral, causes, and which have been from time to time under treatment at the Royal Westminster Ophthalmic Hospital. It is sufficient for the present to say that none of them were in the least benefited by the administration of strychnia.

I will now direct your attention to another series of cases, which although resembling the former in some respects, and ending in white-atrophy, were, so far as could be ascertained, unassociated with a previous meningitis, or other form of cerebral disease; in most instances proceeding insidiously from bad to worse, without even the ordinary symptoms of deranged health, that is, of a sufficiently marked character to attract attention and call for Medical treatment, before the discovery was made that the vision of one or both eyes was nearly lost. Let me add, however, that in such cases it is possible the atrophic condition may have been preceded by some slight intra-cranial pressure. The growth of a very small tumour within the cranium, if situated near the chiasma, or any part of the optic-tract, the cerebral ganglia, or whence the optic nerves arise, will be often more than sufficient to arrest nourishment or cut off the nervous supply. Nay, further, a partial paralysis of some distant part of the body; and which may have occurred during sleep, and otherwise been quite unobserved by the patient; and of which no intelligible account can be subsequently given, or even the temporary interruption to the vascular supply, may end in atrophy of the optic nerve.

Before I conclude my remarks upon this very important subject of the treatment of atrophic forms of eye disease, I think it only right to append a few cases belonging to a class which, according to Drs. Nagel and Chisolm, should have been either cured or greatly relieved, by the administration of strychnia. I refer to that form of atrophy of the nervous tissues associated with retino-choroiditis, and increasing myopia, in other words, atrophy of the retinal and choroidal tissues, with rapidly failing sight, terminating in blindness.

Case IV.—*White-Atrophy, unassociated with Cerebral Disease.*

Sarah C., æt. 20, admitted January 30, 1871. The history given of this case, and which was confirmed by friends of the patient, was as follows:—About fifteen months ago, her general health at the time not being very good, an abscess appeared on the back of her head. Neither surgical nor Medical advice was needed, and the swelling disappeared without breaking. Very soon afterwards she observed considerable loss of sight, especially of the right eye; but as she was quite able to perform her ordinary duties, little notice was taken of it. A few weeks afterwards she found she could not see large objects distinctly, and on mentioning the circumstance to her friends, she was induced to place herself under Medical treatment. Obtaining no relief, but on the contrary, finding the sight getting worse, she applied to one hospital after another, and finally to the Royal Westminster Ophthalmic.

When I saw her she appeared in excellent health, and but for a peculiar stare and dilated pupils, it might have been possible to regard her story with some suspicion. She believed, however, she could just see persons passing between her and the opposite window, but as she also occasionally saw flashes of light, which she mistook for the fire because she was sitting near it, I felt convinced this was merely a mental impression. The ophthalmoscope at once cleared up any doubt, the discs were nearly white, and the retinal vessels very much diminished in size. I thought the case utterly hopeless, but at the solicitation of the patient and her friends I consented to admit her for a limited period. She was placed under the syrup of bromide of iron and strychnia treatment. Mustard plasters were applied daily to the nape of neck, and a solution of calabar bean instilled into the eyes.

Feb. 10th.—No change in her condition. The pupils had, however, resumed their normal state. To stop all medicine by the mouth and inject night and morning 1-30th of a grain of strychnia into the temporal region.

March 4th.—The patient thought she could see, rather better than on her admission, persons passing about the ward.

May 11th.—The strength of the solution increased to 1-15th of a grain; general health and appetite very good.

May 18th.—Considerable headache and twitchings; discontinue the injection for twenty-four hours; then resume.

May 25th.—Severe headache and disagreeable twitchings; discontinue the strychnia. In a few days afterwards I thought it better to stop the injections altogether. At the end of three months, and without having effected the least change either in the appearance of the internal eye, or the condition of vision, she was discharged totally blind.

Case V.—*White-Atrophy, supposed to be owing to a blow received some eighteen months before.*

William G., æt. 44, a seafaring man, from Great Yarmouth, admitted February 22, 1872. The account given by the patient was that about eighteen months prior to admission he received a severe blow over the right eye, and soon after sight began to decline. Only a very slight scar remained, so that it is doubtful whether the blow was a very severe one or exercised much influence on the final result. General health good, and he had always been able to perform his ordinary duty. He was married; no great smoker; had never suffered from any specific disease; on the contrary, had always been a very steady, sober man. As soon as he found his sight decreasing he applied to the Yarmouth Infirmary, but obtained no benefit; on the contrary, one eye rapidly got worse; he was therefore persuaded to come to London for advice. Globes rather prominent; no tension; can just count fingers, and manage to find his way about; no other subjective symptom. The ophthalmoscope disclosed pearly white discs, and very small retinal vessels; the fundus of the right eye presented a less marked atrophic condition than its fellow. With this eye he could, at six inches, make out the largest letters of test types. The hypodermic injection of 1-30th of a grain of strychnia was at once commenced; to take the syrup of bromide of iron and strychnia three times a day.

March 4th.—Right eye slightly improved; can read off No. 20 test types more easily. To continue and gradually increase the strength of the solution to 1-15th of a grain.

April 19th.—Finding he was no better, and that the injection produced some pain and inconvenience, he expressed a desire to leave the hospital, and he was accordingly discharged.

In the autumn of the year he once more presented himself for admission, his sight having in the meantime become worse. He was again placed under the strychnia treatment, as he thought that did him more good than anything he had tried. After some six weeks the drug began to produce disagreeable twitchings and headache, and as he was in no wise relieved or improved, the right eye had now assumed a whiter appearance, he was anxious to return home, and was therefore discharged.

CASE VI.—*Choroido-Retinitis, increasing Myopia, Posterior Staphyloma, and Atrophy.*

Henry J., æt. 37, labourer, admitted Nov. 29, 1872. Had good health until he was about ten years old, when evidences of a weak intellect obliged his friends to send him to an asylum, where he remained ten years. He was dismissed cured, and has not been laid up with any kind of illness since. No history of syphilis or scrofula, has never had a fit, or received a blow on the head. Does not smoke or drink, and has been able to work as a farm labourer until his sight failed. He was always near-sighted, and for the last five years sight has been getting weaker. Pains in the head have been very frequent of late, but without any feeling of sickness. Cannot read the largest test types; believes he can see persons as they pass before the window, and rather near to him. Pupils widely dilated, so that the fundus can be well seen without the use of atropine. Right eye presents well marked appearance of degeneration of the nervous structures; atrophy of nerve. Left choroido-retinitis, and posterior staphyloma; retinal vessels degenerated and looking like so many fine coloured threads, coursing over a pale fundus.

Nov. 30th.—Injection of 1-40th of a grain of strychnia night and morning into temples; to take a mixture of iron and strychnia three times a day; full diet. The strength of the injection was gradually increased, and finally reached 1-10th of a grain twice a day. No bad symptoms followed, although the use of the drug was persevered in for nine weeks. The pains in the head disappeared, but with all our good feeding he appeared to be rather feebler than when admitted. Not the slightest change in vision took place, nor in the appearances first observed in the eyes.

CASE VII.—*Choroido-Retinitis, increasing Myopia, Atrophy of Retina and Nerve.*

Thomas B., æt. 30, a groom, admitted March 16, 1870. Always enjoyed good health; never had syphilis or gonorrhœa; not a great smoker or drinker; general health very good; has always been short-sighted. Lately his sight has been gradually getting weaker; he is constantly troubled by large floating bodies passing before him. He is now incapable of riding out with his master, and cannot see well enough to drive. Is looking pale and anæmic; occasionally troubled with palpitation of the heart and indigestion. Glasses afford no relief. Retinitis-pigmentosa; considerable maceration of the choroid coat. Choroido-retinitis; well marked retinal and peri-papillary degeneration. To take the syrup bromide of iron and strychnia (a).

March 23.—Inject 1-40th grain strychnia into temples night and morning, and gradually increase dose. In this case the strength of the injection reached the 1-5th of a grain of the drug before any unpleasant symptom supervened. Not the slightest benefit resulted from its use; indeed, when the patient left the hospital the atrophy appeared to be rapidly increasing.

CASE VIII.—*Choroido-Retinitis, increasing Myopia, Posterior Staphyloma, and Atrophy.*

Isaac C., æt. 40, a hawker, admitted March 20, 1871. Always near-sighted, and had used glasses for years. General health very good; never laid up for a day with any illness; no syphilis; does not smoke or drink. The last twelve months sight decreasing, so much so that lately spectacles have been quite useless; he sees better without them. Can only read No. 14 test-types (double pica) at three inches; towards evening finds it very difficult to get about. The ophthalmoscope shows that choroido-retinitis has produced considerable maceration, extending in the right eye, partly through the *fovea centralis*. Atrophy of the optic nerve is also more advanced in this eye. His treatment commenced with the administration of iron and strychnia, and the simple continuous battery current. After three weeks this was abandoned, and followed by the hypodermic injection of strychnia, in increasing doses, continued for nearly three months, but no improvement in the patient's condition took place. Lately, and for several months past, he has been taking the bromide of iron with some benefit.

Lastly, I must content myself by directing your attention to the case of a soldier now in the wards, and whose sight is rapidly decreasing from degeneration of the nervous structures. The hypodermic administration of strychnia has been fairly tried in this patient's case also, but without improvement. Indeed, after numerous trials, I can come to but one conclusion with regard to strychnia, that it is utterly valueless in the atrophic forms of eye disease.

◆

THE NATURE AND TREATMENT OF THE CONSTITUTIONAL FORMS OF ECZEMA (a).

By E. D. Mapother, M.D.,
Surgeon to St. Vincent's Hospital.

If the interest attaching to a disease be proportional to its frequency, eczema is most worthy of attention, for one-third of skin diseases are forms of this malady.

The causes and treatment of those forms due to sources of local irritation are thoroughly understood; for example, those due to the action of alkalies in washerwomen, sugar mites in grocers, the flow of tears from strumous eyes, the gravitation of the blood in varicose veins are cured by the removal of the exciting cause and some emollient application, of which bran stupes and bran poultices are the best.

When eczema on the contrary affects large surfaces of the body without any local irritation, is symmetrical, apt to relapse and (as is frequently the case traceable in several members of the same family), some constitutional cause evidently exists, and should be sought for if we wish to treat the disease scientifically. The French call this cause "the dartrous diathesis," dartre being a popular term synonymous with "heat in the blood" in our vernacular; they confess ignorance of its nature and only recognise it by aptness for relapse in eczema and lichen, and psoriasis as well. Ever since I read the following passage in Golding Bird's work I have regarded excess of uric acid in the blood as this constitutional cause. He says, "I have been two or three times consulted in the cases of patients lying bed-ridden from rheumatic gout in whom one or both legs were covered with an eczematous eruption, and the parts on which the exudation from the surface had died had been actually frosted with microscopic crystals of urate of soda."

The following facts seem to me to prove that the gou poison is the cause of eczema:—

1. Many other reliable observers have obtained uric acid and urates from the exudation of eczema, and their increase in the urine in the chronic stage of each disease is undoubted.

2. There is great increase of fibrin in the blood, and it exudes and spontaneously coagulates on the raw surface.

3. Both diseases are characterised by great tendency to œdema and desquamation, which latter, of course, is uni-

---

(a) The syrup of the bromides of iron, quinine, and strychnia, prepared by Messrs. Robbins and Co., 372 Oxford Street, I have largely employed and in many similar cases with excellent results.

a) Read before the Surgical Society of Ireland.

versal in eczema, and occurs in three-fourths of the cases of gout when localised.

4. Gout can be shown to be hereditary in about three-fifths of the cases, and such predisposition can be shown in about an equal proportion of cases of general eczema. The greater proneness of the male sex is observable in both diseases.

5. Every one must have remarked the frequent concurrence of symptoms of gout or of rheumatic gout and eczema. The Chelsea pensioners and the poorer agricultural people of this country exhibit this concurrence on the largest scale. I have seen very few cases of general eczema which had not been preceded or accompanied by what is so well known as acid or gouty dyspepsia.

6. It is an aphorism of Hippocrates that gouty attacks are most frequent in spring and autumn, and the same may be undoubtedly said of eczema.

7. The parts most distant from the circulatory force of the heart and least vascular, for example, the extremities and ears are the most frequent seats of each disease as the urates are most easily deposited.

8. And lastly, the treatment proven to be useful in gout is usually successful in eczema.

Lithia I have found of greatest use as would be anticipated from its extraordinary powers of combining, and dissolving with urate of soda and uric acid. It never fails to act as a diuretic, and the derivative influence from the skin to the more extensive surface of the kidney can be easily understood.

I usually combine colchicum with lithia, but I tried each separately in the following case :—

Patrick Moran, æt. 50, was admitted, Jan. 15th, on recommendation of Dr. Lynch, of Glendalough, to St. Vincent's Hospital. For seven weeks he had suffered from eczema on the front of both the arms and forearms, and of the thighs. He had been constantly subject to acid eructations for years and had drank freely of porter. The urine of the twenty-four hours from 10 a.m. on the 15th, to 10 a.m. on the 16th, was collected, as was that of the succeeding ten days. For the first two days during which no treatment was employed the following was the record :

16th.—Urine, 26½ ounces, specific gravity, 1028 ; acid.

17th.—Urine 24½ ounces, specific gravity, 1030 ; very acid, turbid from urates.

Fifteen drops of wine of colchicum were thence given thrice daily, and on

18th.—Urine, 22½ ounces, specific gravity, 1031 ; very acid turbid from urates.

19th.—Urine, 24 ounces, specific gravity, 1031 ; very acid, turbid from urates.

The dose of the wine of colchicum was increased to 30 drops thrice daily, and for the four following days it produced three or four small evacuations from the bowels daily.

20th.—Urine, 26 ounces specific gravity, 1030.
21st.— „ 40 „ „ „ 1020.
22nd.— „ 37 „ „ „ 1023.
23rd.— „ 20 „ „ „ 1026.
24th.— „ 34 „ „ „ 1030.

On the 24th, as the eczema was not much improved, I prescribed 5-grain doses of citrate of lithia and 20 grains of citrate of potash thrice daily.

25th.—Urine, 49 ounces, specific gravity, 1018, neutral.
26th.— „ 38 „ „ „ 1028, „
27th.— „ 39 „ „ „ 1029, „
28th.— „ 42 „ „ „ 1025, „

On all of the last four occasions the urine was of an inky tint owing to the indigo-blue colouring matter which the free use of carbolic acid ointment had cast off by the kidneys.

The morbid process was at this date almost wholly absent from the parts attacked.

It appears from the details of the amounts and specific gravities of the urine that colchicum has no power of increasing the excretion of the solids of urine, and indeed, it is now generally believed to check the formation of urea and uric acid, a fact anticipated by the sagacity of Dr. Graves (*a*), whose physiological deductions were so remarkable.

In inveterate cases of eczema arsenic may be necessary, and that metalloid is of great repute in chronic gouty and rheumatic affections.

Lastly, sulphur internally and externally, especially when used in the waters of Harrogate, Leuk, in Switzerland, and Lisdoonvarna, nearer home, is of equal efficacy in gouty and eczematous affections.

A few words about external treatment : carbolic acid diluted with seven parts of lard keeps the skin pliable, prevents suppuration and fœtor, and has probably some astringent power.

In cases of universal eczema which are rare, indeed, with the exception of one I saw a month since in St. Louis Hospital, Paris, I have never met one, starch baths, or still better, bran baths are called for, to check the excessive cutaneous transpiration.

I have then striven to show that constitutional eczema depends on the gouty diathesis, and should be treated according to the well-known therapeutic indications observed in that condition.

Hospital Reports.

WEST LONDON HOSPITAL.

Case of Diabetes Mellitus.

(Under Dr. Thorowgood. From notes by Mr. Bridgman).

Ada C., æt. 18, came as out-patient to the West London Hospital, January 30th, 1872. She is small, and of fair complexion, and complains of troublesome eruption of acne, with dryness and harshness of her skin. Her father and mother are living and healthy, brothers healthy, two of her grand-parents living, two are dead, but patient does not know of what they died. Patient has lived a steady life, she began to menstruate when fourteen years old, and has been regular ever since. She was quite healthy up to three months back, when she began to lose flesh and appetite, and her friends noticed that she was in bad spirits. At present she complains of feeling languid, of great thirst, loss of appetite, and of passing much more water than she used to. Her skin is dry and scaly ; her tongue red and chapped ; patient has no cough, and the physical signs of chest are normal.

February 6th.—Patient's condition the same ; water brought was pale in colour, sp. gr. 1040 ; gave an intense mahogany tint with Moore's, and threw down quantities of sub-oxide of copper with Trommer's, test.

7th.—Patient was admitted to the hospital. During the first twenty-four hours she was placed on ordinary diet, and she passed 10¾ pints of urine, with a sp. gr. 1042,

8th.—Patient was dieted on 6 oz. of meat, 3 pints of milk, 3 gluten biscuits, toasted bread, water cresses.

9th.—Urine 10 pints.

10th.—9½ pints.

11th.—9 pints.

12th.—6 pints, sp. gr. 1045.

13th.—10 pints, sp. gr. 1042. Patient takes her diet very well, and thinks she feels better ; temp. 98·8.

℞ Pot. cit., gr. xv. ;
Pot. brom. gr., v. ;
Aquæ camph., ℥j. *ter die.*
Ol. morrhuæ ʒij. Omni nocte.

14th.—Temp., 98·6 ; passed 10 pints of urine ; sp. gr. 1040 ; urine contained 37 grs. of sugar in ℥j., or 740 grs. in Oj., therefore the 10 pints passed in the twenty-four hours, contained 15 ozs. 3 drs. 20 grs. The fermentative test was the one used.

(*a*) "Clinical Medicine."

15th.—Temp., 98·2; urine passed, 9½ pints.

16th.—10 pints.

17th.—11 pints, with sp. gr. 1040.

18th.—10 pints.

19th.—12 pints.

20th.—10½ pints; pulv. opii, gr. j., in pill, to be taken every night; meat discontinued; milk increased to Ovj.

21st.—12½ pints, sp. gr. 1036.

22nd.—10½ pints.

23rd.—10½ pints. To day the patient was weighed, and found to be 6st. 8lbs.; she says that a year ago she weighed 7st. 12lbs.

24th.—12½ pints, sp. gr. 1034; pulv. Doveri, gr. v., substituted for the pill at night, and a tepid bath ordered. Mixture changed to

℞ Ammon. carb., gr. vj.;
Sodæ bicarb., gr. xij.;
Aquæ camph., ℥j. t. d.

25th.—13 pints, sp. gr. 1036. Patient felt rather weak after the bath, but there was not the slightest perspiration.

26th.—13 pints, sp. gr. 1036.

27th.—13 pints.

28th.—13 pints.

29th.—14½ pints, sp. gr. 1040.

March 1st.—14½ pints, sp. gr. 1036. Patient has had a considerable bleeding from nose.

2nd.—13½ pints. Mixture changed to

℞ Sodæ hypophosph., gr. v.;
Ferri citrat., gr. v.;
Pot. cit., gr. x.;
Aquæ menth. pip., ℥j. t. d.

The patient has had the tepid bath about every third night, but it has never produced any perspiration. There are patches of pityriasis on both arms.

3rd.—14¾ pints.

4th.—17 pints, sp. gr. 1034.

5th.—15½ pints. Mixture changed to

℞ Liq sodæ arseniatis, ♏iij.;
Sodæ bicarb., gr. viij.;
Inf. calumb., ℥j. t. d.

6th.—16½ pints.

7th.—17 pints.

8th.—14 pints. Patient was again weighed and found to be 6st. 6½ lbs.

9th.—15½ pints, sp. gr. 1036.

10th.—16½ pints; liq. sodæ arseniatis, increased to ♏v. at each dose.

11th.—16 pints.

12th.—15 pints; temp. taken was 97·8.

13th.—15 pints, sp. gr. 1034.

14th.—15 pints, sp. gr. 1034; temp., 98·6. The temperature was taken frequently through the case, but as a rule it was just normal, where worthy of note it is recorded. Patient complained of pain over the region of the liver posteriorly, the part to be painted with iodine.

15th.—13 pints, sp. gr. 1038; temp., 98·6.

16th.—12 pints, sp. gr. 1034; temp., 99.

17th.—13 pints, sp. gr. 1033.

18th.—13 pints, sp. gr. 1033.

19th.—12½ pints, sp. gr. 1032; temp., 97·8.

20th.—10 pints, sp. gr. 1032. Gluten biscuits obliged to be discontinued.

Up to this time the patient had been in the habit of getting up for a few hours during the day, but now she began to prefer remaining in bed.

21st.—10 pints, sp. gr. 1034.

22nd.—11½ pints, sp. gr. 1032.

23rd.—8½ pints, sp. gr. 1031.

24th.—7½ pints, sp. gr. 1031.

25th.—7½ pints, sp. gr. 1030. Patient has been sick two or three times after taking food, and complains of loss of appetite, which until the last few days has remained good; tongue quite dry; pulse 88, temp., 98.

26th.—6½ pints, sp. gr. 1030. Patient has been sick several times since yesterday; tongue dry; pulse, 100; temp., 98·6. Mixture changed to

Pot. iodidi, gr. iij.;
„ cit., gr. xii.;
Aquæ menth. pip., ℥j.

Evening.—Vomiting has continued; no food has been taken.

27th.—5 pints of urine passed with sp. gr. 1028; vomited once this morning; tongue dry and brown; pulse, 100; total loss of appetite; bowels not open.

28th.—Passed 4 pints of urine, with sp. gr. 1028; slept well; complains of pain in the region of the heart; breathing laboured; face pinched and dusky; pulse 108, very small; temp., 97 (*a*); takes nothing but a little milk with ice in it; bowels still not open; ol. ricini, ℥ss. ordered.

28th.—*Evening.* Patient has grown much worse since the morning; face very dusky; lips blue; breathing quick and gasping; breath cold; extremities cold and blue; pulse remains about 100, is very small; patient takes a little brandy and soda water, and iced milk.

The patient lingered until 6.30 p.m. on the 31st. During the last forty-eight hours she was quite unconscious, generally lying quite still; respiration very laboured; breath cold; surface cold and blue. The urine, which certainly did not measure a pint, was passed in the bed.

Post-mortem.—None of the organs (with the exception of the kidneys), presented any abnormal appearances. The kidneys were large, pale, and flabby, shelling very easily out of their capsules. The liver appeared quite healthy, both as regards colour, texture, and size. The bladder was empty and contracted, the walls rather thicker than usual. The brain and spinal cord appeared quite healthy. Dr. Dickinson took such portions of them as he required for microscopical examination.

Remarks.—Dr. Thorowgood from the first, was disposed to take an unfavourable view of Ada C——'s case, owing to the fact of the disease having somewhat rapidly developed to a high degree in one who was quite young. Having observed more than once, that when a patient with diabetes can be caused to perspire freely, there is nearly always amendment, efforts were made in the present case, to bring about sweating by the frequent use of the hot bath, and when first admitted, she had a mixture of nitrous ether with nitric acid, which after a week or so was changed to the bromide of potassium, with citrate of potash. The heavy semi-typhoid look of the patient, might have been perhaps improved by this mixture, but it cannot be said that from any of the means employed, any marked results towards cure were obtained.

Transactions of Societies.

DUBLIN PATHOLOGICAL SOCIETY.

[SPECIALLY REPORTED FOR THE MEDICAL PRESS AND CIRCULAR.]

The usual meeting of this Society took place on Saturday, February 15th, 1878.

The President, Dr. KIDD, in the Chair.

Dr. HAYDEN said the specimen he wished to bring under the notice of the Society was an example of

CANCER OF THE OVARIES.

The woman was aged 53, married a few years, but never had children. Menstruation had ceased for some years. Six months previously to her admission into hospital, which took place on the 26th of January, she told him that she for the

---

(*a*) This temperature was taken twice to make sure there was no error. It would have been interesting to have taken the temperature again shortly before death, when I have no doubt a much lower temperature would have been registered, but the friends were constantly with the patient, and did not like having her disturbed.

first time noticed a swelling of what corresponded to the anatomical region known as right iliac. It grew rapidly, and six months afterwards the abdomen had attained the dimensions which are exhibited at the full period of pregnancy; it was attended from the first with rather a severe pain. The woman was weak in the last degree—so much so that death was evidently impending. She had scarcely a pulse, her face was congested, and the lower extremities œdematous. She complained of constant aching pain in the abdomen. By means of an opiate he succeeded in obtaining for her a short sleep in the course of that night, and on the following day, in the evening, she died of asthenia. There were certain circumstances connected with the case which were worthy of notice, and which induced him to diagnose malignant disease of the ovaries. The rapid growth within six months, the occurrence of continuous pain from the first appearance of the swelling to the termination of life of the patient. The tumour was irregular in outline, and unequal in consistence, the lower portion being firm but elastic, and the other composed of a number of distinct fluctuating cysts. Both lumbar regions were resonant on percussion as the patient lay upon her back, whilst the anterior portion of the abdomen was universally dull. The tumour when removed was three or four times as large as they then saw it; they would observe that it was connected with both ovaries, but more especially with the right, and the patient very properly had described the tumour as having commenced on the right side. The uterus was of the ordinary size of a woman who had never borne children. The Fallopian tubes on both sides were normal, but the ovaries had entirely disappeared, or rather were converted into groups of distinct cysts of great magnitude. On the right side several of these would have contained a quart of liquid, and were filled with a honey-like substance of the consistence of jelly. Under the microscope this substance was seen to consist of a fine fibrous stroma, in the meshes of which the proper colloid substance, composed of nucleated cells, escaped nuclei, and fat granules, was deposited. The upper portion of the tumour contained several large sero-cysts containing a clear and thin fluid. The cyst-walls throughout were composed of dense white fibrous tissue. The mesenteric glands were infiltrated with medullary cancer, mottled here and there with melanoid pigment. On suction they yielded a cream-like juice, which presented the ordinary histological elements of medullary cancer. The left one was also affected, but in a less degree. There were certain masses connected with the left ovary. The case was of interest therefore both diagnostically and pathologically. The diagnosis of malignant disease of the ovaries was made, as already stated, from the two-fold circumstance of the rapid growth of the tumour and the early occurrence of pain. The pathological interest of the case had reference to the union of colloid and medullary cancer, with the addition of dark pigment, formerly regarded as a distinct form of cancer under the name of mellanoid, in the same subject; and the further existence of serous in conjunction with these.

Mr. **Frank T. Porter** exhibited two

STYLOID PROCESSES, UNUSUALLY ELONGATED.

They had been removed from a female subject over thirty years of age. Each process was united to the temporal bone by cartilage—a rare occurrence, as bony union generally existed between those parts. The stylo-hyoid ligaments and muscles were absent. In the same subject the right occipital artery came off from the pharyngia ascendens, and not external carotid, which was usually the case.

Dr. **Robert Smith** made a communication on a peculiar operation for amputation through the Tarsus, adopted in a case of gangrene of the foot.

Dr. **Quinlan** also exhibited a specimen taken from a patient suffering from stricture.

We hope to publish both these communications in our next.

THE SURGICAL SOCIETY OF IRELAND.

The Society met on the evening of Friday, 31st January.

The President, Dr. Kirkpatrick, in the Chair.

Dr. Jacob read a paper

ON THE ACCIDENTS IN FLAP EXTRACTION OF CATARACT, AND THE METHODS OF AVOIDING THEM,

which will be found *in extenso* at p. 153.

Mr. **Swanzy** said it appeared to him that Dr. Jacob had not established satisfactorily the equal success of the linear extraction and the flap extraction. With the exception of the dictum of Mr. Loring he had not brought forward any fact which could bear him out, and he (Mr. Swanzy) was not sure that implicit faith was to be placed in Mr. Loring, although he was a very distinguished and clever ophthalmologist, but when it was remembered that the whole of Europe and America had forsaken the flap extraction and had adopted Von Graefe's operation or some one very closely allied to it, that was sufficient to justify them in doubting the accuracy of Mr. Loring's statement. Dr. Jacob placed the highest importance on the ripeness of the cataract for flap extraction, because if not mature, some of the cortical substance might remain behind and produce secondary iritis. He (Mr. Swanzy) had no doubt of this, but one of the greatest advantages which Von Graefe put forward for his own operation was, that it was not necessary to wait for the cataract to become ripe. They all knew the length of time it took for the cataract to arrive at maturity, and it was therefore a great advantage that they should be able to extract cataracts without any danger to the eyes of the patient and without any fear of secondary iritis, instead of keeping the patient in misery for months before the operation could be attempted. And they could do this although some portion of the cortical substance remained; for they were able to get this out by the motion of the lids without the use of instruments. Even if portions of the cortical substance were left behind in linear extraction there would be no danger of secondary iritis, but they were able to remove them from the portion of the wound, and in fact, the iris was out of the way. No doubt, the flap extraction was the queen of all cataract operations. When successful there was nothing to approach it; but the point to think of was the percentage of successful cases. Dr. Jacob did not expect to reach anything higher than 70 per cent. That was not to be compared with 95 or 97 per cent. of succesful cases in linear extraction, although the latter was rather an inferior operation to flap extraction; and that was the success attained by Professor Arldt, of Vienna. Of these, 4 per cent. were not complete, the people saw very well, but it was called an imperfect success, but on the whole his successful operations were between 95 and 97 per cent. That was higher than Von Graefe reached himself. When he (Mr. Swanzy) was in Vienna in 1857 Professor Arlt was only commencing to adopt Von Graefe's operation. He had been most distinguished as an operator in the flap extraction, and had made his reputation by that operation; but although such a very distinguished flap extractor he had entirely given it up, he never thought now of performing it; he had tried other operations but he had given all up for Von Graefe's linear extraction, and it was with that he got 97 per cent. of successful cases. With regard to anæsthetics in eye operations and especially in cataract operations, he (Mr. Swanzy) never used any anæsthetic, not even ether in the extraction of cataract. He did not think there was any benefit gained by it. With proper fixation the operator could get the eye perfectly quiet, and by talking to the patient he could acquire such a moral influence over him as to retain the eye in the one position. Immediately the operation was over it was desirable that the patient should have all his senses about him to make use of certain tests of vision, which restored confidence to him and eased his mind so much that the healing of the wound went on much better. It was a great thing also that the patient's friends should see him counting his fingers for instance, whereas, before he was perfectly blind. There was nothing, in his opinion, to be gained by anæsthetics, whereas, there was something to be gained by not using them. Fixation was one of the greatest modern improvements in cataract operation, but no doubt to be beneficial, the fixation forceps must be a good one and must be properly managed. Dr. Jacob brought two operations together that ought to be kept perfectly separate. He spoke of the scooping extraction and Von Graefe's modified linear operation. These, however were quite different. In the scoop operation an instrument was introduced into the eye to remove the cataract; whereas, in the linear extraction there was nothing of the kind, it might be accompanied by iridectomy, but there was no such thing as the introduction of an instrument, and the cataract was removed altogether by pressure on the eyelid. These two things should be kept perfectly distinct; and it seemed to him that seven cases of Graefe's extraction were hardly sufficient to enable one to form an opinion as to the advantage of the operation. It would be fair to perform 100 of these operations and 100 of the flap operations and then draw a comparison between the two.

Dr. Stewart said he looked back with great pleasure to his experience of Dr. Jacob's father's practice when he (Dr. Stewart) was a student in the years 1825, 1826, and 1827. The ease and certainty with which he performed the operation for the removal of cataract were remarkable. There were no anæsthetics in those days, but such was the confidence felt in Dr. Jacob that the patients would remain as quiet under the operation as if they were merely going to be bled.

Prof. Morgan would like to have some information as to the relative tests by which the success or non-success of the different operations referred to was measured. It would be quite a different thing if one test were applied to the linear and another to the flap operation, and as there had been some doubt thrown out on this point, he should be glad to have it explained. As to the ripeness of the cataract the importance of which, in the flap operation, was so strongly dwelt upon, he would suggest whether it might not be a good thing to pass a needle through the lens, make it a traumatic cataract, and then, without waiting for several months, proceed to perform the operation? He should like to know whether there were any statistics of the results of iridectomy in combination with the linear operation in cataract, in order that they might judge whether it deserved the laudation it had got and was of that favourable nature which its advocates alleged. He would also like to hear from Dr. Swanzy if he had seen the linear extraction performed as frequently here as abroad? They were aware that ovariotomy which had been so successful abroad was not equally successful in Dublin, owing possibly to some peculiarity of diathesis; and therefore he should like to know whether the operation introduced by Von Graefe had been as successful under Dr. Swanzy's hand here as it was abroad.

Mr. Swanzy did not think he had been long enough in this country to form an opinion from his own practice. The operation had been frequently performed in London and in Dublin also it had been extensively performed, and as far as he was aware the operation gave as much satisfaction as any other operation for cataract. Of course each practitioner had a way of his own of performing the operation, but these were only the slight differences to be met with in every operation.

Dr. Walsh said that the statistics in the able paper read by Dr. Jacob startled him a little. He was quite convinced that the most careful and elaborate reports gave very different results; according to his recollection there not being 5 per cent. of failures in the linear and as many as 25 in the flap extraction. Dr. Jacob appeared to him not to have attached sufficient importance to a more recent method than either of the above. He alluded to one originally performed by Warlomont, which he briefly stated consisted in an incision through about the centre of either the upper or lower section of the cornea through which the lens is extracted, the pupil being dilated as widely as possible with atropia. In this operation the liability of suppuration of the cornea is lessened considerably, an important point, as suppuration was a fertile source of failure in flap extraction. It moreover got rid of the necessity of incising any portion of the iris which was one of the principal objections made by Dr. Jacob to the linear operation. He had had some experience of Warlomont's operation, and he thought it had some other decided advantages, not the least of which was its simplicity and facility of execution even by comparatively unskilled operators, a fact of great importance to those in remote districts or abroad.

Mr. Kelly said he would not discuss the relative merits of the linear and flap operations further than to remark the opposite views the followers of the two methods attached to incisions of the iris. In flap operations one of the most rigid injunctions was to avoid implication of the iris in making the incision, while Von Graefe's operation includes as an essential step its free division. Pathology, experience, and analogy indicate the excessive stringency of the interdiction. Ambi-dexterity, he thought, could be acquired easily and without risk. Experience would quickly demonstrate the interesting fact that the left, or least used hand, when guided by concentrated thought and will, readily acquired a facility of motion nearly equal to the right or more serviceable member when under the same surveillance. In other words, should the right hand be placed under critical observation it lost that freedom and precision which was acquired by the experienced operator who was unconscious of the independent movements necessary for the accomplishment of any act of manual dexterity. To a similar condition the left hand could be raised. Except with one of Nature's operators surgeons were vividly conscious of the steps of any given procedure. Hence, if the experiment be made with an unprejudiced mind, most men would be pleased with their progress in ambi-dexterity. A point on which Dr. Jacob did not dwell was the laceration of the capsule in the flap operation. It might be regarded as a theoretical nicety to attach importance to the shape of the laceration, but the prescribed form was crucial. He (Mr. Kelly) had no doubt that this could be adhered to readily. A modification of this laceration, based on mechanical principles, was to tear the capsule transversely first a little below the equator and then to confine the vertical laceration to the upper segment of the capsule, By this means the lens, instead of entering the anterior chamber *en masse*, was necessarily tilted forwards and upwards towards the corneal incision. Any additional measures to extract the lens were facilitated and even regulated by this inverted T laceration. The expediency of directing the point of the triangular knife towards the centre of the imaginary globe of the cornea increased as the cornea flattened, and the neglect of this precaution in many instances would cause a most perplexing inequality between the external and the internal lips of the corneal incision. In considering the exhibition of anæsthetics they were not justified in excluding chloroform. Every surgeon was aware of the troublesome emesis sometimes occurring during its administration. Exemption from this phenomenon was claimed for ether, but until its absence was fully established he (Mr. Kelly) did not think (unless in very exceptional cases) an oculist was justified in incurring the additional danger of the escape of the vitreous humour.

Dr. Jacob in reply said he was much pleased that a communication of his on a subject which could not be supposed to interest very much a Surgical Society had elicited so valuable a discussion, particularly as they had had the opportunity of hearing the views of Dr. Morgan and Mr. Kelly who did not apply themselves exclusively to that branch of surgical practice. As to what Dr. Walsh had said relative to further modifications of the linear extraction, he was well aware of them, but he did not think it necessary to enter into details. If it turned out by experience that these operations could be performed with more certainty of success, he thought they would supersede flap extraction, because they possessed the advantage of not necessitating iridectomy. He looked upon the removal of a portion of the iris as a blemish.. An eye never had the same appearance afterwards as before, and the acuteness of vision obtained in the best circumstances with an iridectomy operation was not equal to that obtained by a successful suction operation, or a successful flap extraction. He did not, however, attach too much importance to that point, and if it could be shown that there was a distinct and unequivocal balance of success on the side of the iridectomy operation he would yield to the stress of numbers and abandon flap extraction. He was doubtful on that point. If Arlt had achieved 97 successes he was afraid it proved too much. It was hard to believe they were measured by the same standard as was applied to the flap extraction. That was the very point to which Dr. Loring had applied himself. He took Prof. Von. Graefe's statistics and showed that when in one instance a vision of one-fourth was considered a success, in another instance a vision of one-sixth was considered successful: and the very same result which in one class of cases was regarded as failing was regarded in another class as success. Therefore it was that Mr. Loring said the alleged superior success of modified linear extraction was derived from the garbling of statistics not borne out when rigidly tested. Mr. Swanzy that said all Europe had abandoned flap extraction for iridectomy; but that statement must be modified a little. He found in the work of Mr. Wolfe, of Aberdeen, a statement which was exactly the reverse. In the records of the Ophthalmic Congress of 1868, M. Otto Becker, of Vienna, stated that he found 217 operations for cataract mentioned, 150 of which were performed by Prof. Arlt, and 117 were successful, and 45 accompanied by more or less serious accidents. Prof. Quagliano, of Pavia, denounced the modified linear operation as in no respect superior to that of flap extraction. Prof. Hansen and Dr. Bell Taylor had done the same thing, and in the *Annales d'Oculistique* of July last M. Warlomont states distinctly that, on inquiry from all the leading English oculists, he ascertains that the modified linear operation was no longer performed in its entirety, but that the peripheric incision was being universally abandoned. He (Dr. Jacob) was of opinion therefore that the verdict of "all Europe" was not in favour of Von Graefe's linear extraction. He could not form an opinion on linear extraction from his own experience in only seven cases, but he was not disposed to try it in one hundred as Mr. Swanzy suggested. He was disposed to hold to the operation in which he had met with success, rather than purchase experience by sacrificing more eyes. As to ambi-dexterity he confessed he had not acquired that, and he knew no reason why the left eye could not be well operated on from before. He was sure he could not make a good flap section with his left hand, and he saw no reason why he should not operate with the other. Therefore, he should not like to earn experience in that way and train his left hand at the expense of his patient. As to the laceration of the capsule of which Mr. Kelly spoke his theory was ingenious, but the laceration of the capsule, as a rule, was not a difficult matter. He continued the act of laceration until he observed that the lens had pressed a little forward and then he knew it had burst the capsule. He did not proceed in any particular direction with his incision into the capsule, though, perhaps, he might be more successful if he adopted Mr. Kelly's suggestion. As to the danger of which Mr. Kelly had spoken of getting the knife between the layers of the cornea, he said he made his incision as close as he could to the iris without touching it, and so entered the anterior chamber, almost perpendicularly to the cornea, and he had never seen his knife pass through any greater section of the cornea than was desirable. Having latterly been engaged in looking up the literature of this subject, and having been impressed with the value of the old operation and believing that it ought not to be cried down without good grounds, he had thought it right to put forward his views in the paper he had read that evening.

Dr. **Mapother** read a paper on

THE NATURE AND TREATMENT OF THE CONSTITUTIONAL FORMS OF ECZEMA,

Which will be found *in extenso* at page 156.

Dr. **Eames** said that he thought Dr. Mapother gave too great prominence to the connection between general eczema and gout. No doubt these two diseases were frequently found combined; but on the other hand he (Dr. Eames) had met with very many cases in which no such alliance of eczema could be traced. Indeed, he was inclined to believe that struma had much more to do with the causation of eczema in young subjects, and in those of the lower ranks of society who presented themselves at our dispensaries than gout had. When the relation of cause and effect could be clearly traced between eczema and gout it was questionable how far the physician was justified in healing the eruption by means of topical remedies.

Dr. **Benson** considered there was an intimate connection between gout and eczema. A few years ago he had to treat a gentleman dreadfully afflicted by gout, manifesting itself in dyspepsia and a derangement of every part of his system, not showing itself very much in the joints but rather in general constitutional disturbances, and in some few instances the joints did show it. He was so terribly afflicted by the disease that his life was made miserable by it, and in some instances endangered by attacks in the head and stomach. At length eczema began to show itself in various places; it covered the greater part of his body, his face and hands excepted, and from that moment he never had any symptoms of gout for two years until the eczema disappeared, and then some few symptoms of the gout returned. That case, with the recollection of others of a somewhat similar kind, convinced him that there was an intimate connection between the two diseases; that eczema was the outward manifestation of gouty poison, and he found that eczema was much benefitted by the remedies he used under the impression that it was a gouty affection.

Dr. **Mapother** in reply said the experience of every hospital surgeon would contradict the assumption that gout was a disease to be found exclusively among the aristocracy. Gout was due to a great many other causes than luxurious living. Want of exercise and a damp climate, and many other circumstances contributed to produce it; and it had been remarked that within the last ten or fifteen years since the people of this country had taken to drink ale and porter largely they had become more afflicted with gout than formerly. Rheumatic gout, which was due to uric acid in the blood was the great disease of this country; and he found on looking over the work of Garrod, the great authority on gout, that a good many of his patients were Irishmen. As to eczema being frequently scrofulous he did not think the general eruptions on the surface of the body were so; and the only form of eczema he had seen in scrofulous patients was that localised one caused by the scalding tears from scrofulous ophthalmia. In no instance which had come under his observation when there was glandular enlargement in connection with eczema did the glands suppurate. He was glad to be borne out in his view by Dr. Benson. The case mentioned by that gentleman showed there was an eliminative effort to throw out the gout by eruption on the surface.

The Society adjourned.

THE MEDICAL SOCIETY OF LONDON.

Monday, January 27th, 1873.

Thomas Bryant, Esq., F.R.C.S., President, in the Chair.

Mr. **Thomas Henry Hill** asked leave to make some remarks with reference to Dr. Thorowgood's treatment of obstruction of the bowels; since the last meeting he had suggested the use of acetate of lead in combination with belladonna, in a case of obstruction, and in twelve hours there was a profuse action of the bowel, with complete relief.

Dr. **Sansom** showed

A PATIENT WHO HAD BEEN THE SUBJECT OF EXTRA-THORACIC SUPPURATION, WITH DISCHARGE INTO THE LUNG.

R. B., æt. 37, applied at the Royal Hospital for Diseases of the Chest, as an out-patient, on Nov. 1, 1872, suffering from debility and cough, with expectoration of much thick phlegm. Four years ago she had a miscarriage, and had never been well since, extreme languor and shortness of breath succeeded any exertion, and six weeks before her admission she noticed a swelling above the right collar-bone, recurring after a violent cough. Auscultation and percussion failed to elicit any evidence of general pulmonary lesion; but above the right clavicle there were obscure cavity sounds; close to their situation was a limited oval swelling, evidently glandular; and below the clavicle a diffuse fulness was noted. The patient was admitted on the 4th. The glandular swelling was now tender and painful, and throbbings were experienced in the infra-clavicle fulness. Dr. Sansom did not consider the cavity (which was evidently of very small extent) in the right apex, tubercular. The patient presented no phthisical sign; the cough was violently paroxysmal, and it was quite clear that for long periods it had remained in complete abeyance. He was disposed to think the occasional large *râles*, and amphoric sounds heard above the clavicle, due to a dilated bronchus or ruptured air cells. He considered that suppuration was taking place in or around the inflamed gland. Under rest and emulcents and expectorants the cough and expectoration entirely ceased after four days, but the local tenderness increased and became exquisite. Liniment of iodine was applied, but could not be borne.

Nov. 22nd.—Deep fluctuation was noticed over the swelling. Poultices were adopted, and iron and quinine administered.

On the 6th Dec. suddenly occurred the expectoration of half a pint of pus, the cough being accompanied by a peculiar rattling felt, as well as heard, in the supra-clavicular region. Swelling had, to a great extent subsided. Auscultation revealed gurgling with a crackling sound on coughing, and pressure of the finger produced a feeling of large crepitation.

On Dec. 21 all swelling had subsided as well as all the signs and sounds; and tenderness had almost gone.

On the 10th January, 1873, fluctuation and tenderness were again manifested as previously, and on the 17th occurred a second copious expectoration of pus. The patient, who is still under care, suffers yet from severe cough, with occasional expectoration of rather fœtid purulent phlegm, the supra-clavicular prominence has largely subsided, but the finger still readily detects the crackling sensation produced by a cough, and gurgling is still heard. Over all the rest of the thorax the sounds are quite normal.

Dr. **Semple** thought there was a large gland pressing upon the subclavian artery.

Dr. **C. T. Williams** would have said there was a suppurating cavity, had he not heard the history of the case; probably there was an abscess which had broken into the lung tissue.

Dr. Sansom said that against the hypothesis of phthisis, the facts of absence of phthisical prodromata, the persistence of fair weight and menorrhagia were important; physically, the signs were those of cavities.

Mr. Royes Bell asked if there were rigors, and whether the temperature was high?

Dr. J. Milner Fothergill remembered a case in which a fluctuating tumour appeared over a man's loins. Soon after, violent coughing ensued, and expectoration of enormous quantities of pus. It was evident that the lumbar abscess communicated with the lung. The man recovered after a like occurrence on the other side of the loins.

Dr. Habershon then read three instances of

AORTIC DISEASE

which had recently come under his care, and showed the pathological specimens. The first was that of a man, æt. 39, who had suffered from repeated attacks of rheumatism. When admitted into Guy's Hospital in August, 1872, he was suffering from urgent dyspnœa and cardiac distress, with œdema of the lower extremities; a loud double bruit was audible over the aortic valves, and in the course of the aorta, but after a few days the bruit changed in character, and became a continuous sound. He died on the 10th September, and on inspection the aortic valves were found to be extremely diseased, one was contracted and everted, the valve nearest the pulmonary artery was thickened, ulcerated, and covered with fibrinous vegetation; an ulcerated opening immediately above the valve extended into the pulmonary artery, the edges were irregular, and the opening was partially blocked up by fibrine. The mitral was thickened, but other structures were healthy. Dr. Habershon referred the changed character of the sound to the ulcerative communication between the aorta and the pulmonary artery. The second case was that of a man, æt. 56, who was brought to the hospital in a dying state in December, 1872, he had been engaged in labourer's work, and dated his last illness to a cold taken at Christmas, 1871; dysphagia came on two months before death, and gradually increased in severity. The patient suffered from dyspnœa and severe pain between the shoulders; there was now a short systolic bruit audible at the apex of the heart. The prostration was extreme when he was admitted. The aorta was found to be much diseased, especially in the ascending and transverse portion of the aorta, the vessel was enormously dilated so as to admit a man's fist, on the right side, immediately above the valves, a pouch extended to the right, and the lung in contact with it was sloughing. Other lobules of the lung were in a similar state. At the commencement of the ascending aorta an angle was formed by the contraction of the pouch, and at this part pressure had been made upon the left bronchus and upon the œsophagus; an oval communication, an inch in length, existed between the two canals, and the ends of the bronchial cartilages projected into the œsophagus. The third instance was a very remarkable one, in which multilocular aneurism of the ascending portion of the arch of the aorta existed. The sac extended behind the sternum, and occupied the normal position of the heart; it perforated the ribs, and a third false sac formed, a pulsating tumour existing from the left side of the sternum below the left nipple in the direction of the axilla. Death resulted from the perforation of the post-sternal sac into the left pleura. The patient was 55 years of age, he dates his illness to a blow on the chest, and afterwards he suffered from pain about the left breast especially on exertion. The attacks became more frequent during the last year of his life, and three weeks before admission into the hospital, at the end of October, 1872, he noticed a swelling in the precordial region. This swelling rapidly increased in size, and became as large as both fists and pulsatile in character. Darting pains came on with dyspnœa and distress, and when hæmorrhage into the pleura occurred, he speedily sank. The aorta was found to be dilated and atheromatous, and two inches above the valves was an opening three inches in circumference which passed into an aneurismal sac, and then into the subcutaneous sac, the latter opening being between the third and fourth ribs. Forty ounces of clot and much serum were found in the left pleura. The question of differential diagnosis between aneurismal and vascular malignant growth was briefly dwelt on, but the result showed the original opinion of aneurismal disease to have been correct.

The President asked whether, in the third case, a mistake might not have arisen between it and pulsating tumour of bone, could Dr. Habershon give any means of diagnosis between such cases?

Dr. Habershon thought the question of differential diagnosis of aneurismal disease, one of great importance, and it had specially arisen in the second case. In the third case the dulness was more defined than in most tumours of the chest.

Dr. Broadbent thought that thanks were due to Dr. Habershon for his excellent cases, and would ask whether in the first case the opening into the pulmonary artery was congenital. The right ventricle was very small, and gave rise to the thought—then, again, there was ulcerative endo-carditis, it was ill-marked. The pulmonary artery was small also, he thought the opening was congenital, and that the left ventricle had supplied both general system and lungs for a great part of the patient's life.

Dr. Routh asked whether Dr. Habershon attributed the change in sounds to sudden disease, if so, it did away with Dr. Broadbent's hypothesis.

Dr. Semple thought Dr. Broadbent's a very reasonable explanation, ulcerative endo-carditis was extremely rare.

Dr. C. T. Williams asked Dr. Habershon what was the cause of death in the third case? The aneurism did not seem to have given way anywhere.

Dr. Habershon thought Dr. Broadbent's explanation was very interesting, but the case was supposed not to be congenital because a systolic and diastolic bruit was heard, which afterwards changed to a continuous blowing murmur. He thought ulcerative endo-carditis was not very uncommon.

Dr. Williams then showed

A PATIENT ILLUSTRATING TAPPING FOR EMPYEMA.

The patient, a man, æt. 29, was admitted into the hospital at Brompton, on the 4th of July, 1871, with a history of pleurisy of four and a-half months standing, and with signs of extensive effusion into the right pleura. The right side measured one and a-half inches through the mammary region, more than the left. The dyspnœa was great, and the pulse rapid.

On the 10th of July he was tapped by Sir Wm. Fergusson, and four pints of purulent fluid were taken away with temporary relief, but fresh accumulation took place, and an abscess formed in the mammary region, which was opened by Mr. Bartlett, and found to communicate with the pleura, through a channel passing between the two layers of the intercostal muscles which acted as a valve preventing the entry of air. In spite of this mode of exit, the matter rapidly accumulated, the valve was rendered insufficient, air was admitted and the discharge became offensive. The patient became much worse and began to show symptoms of pyæmia.

On the 21st of Aug., Mr. Henry Smith made a second opening in the posterior wall of the chest and passed a seton through; this greatly increased the discharge and also its offensive odour. On the 24th, at the request of Dr. Williams, Mr. Henry Smith introduced a drainage tube, and injected a solution of carbolic acid into the pleura. The effect of this was that the discharge became serous, small in amount, and free from smell, the pyæmia immediately disappeared and the man made a rapid recovery. Dr. Williams strongly recommended the use of the drainage tube in cases of pyæmia, and especially if rapid formation of pus took place.

Dr. Douglas Powell, Dr. Sansom, Dr. Wiltshire and Mr. Royes Bell, took part in the discussion which followed, to which Dr. Williams briefly replied.

◆

STUDENTS' COLUMN.

SYNOPTICAL REVIEW OF THE OFFICINAL PREPARATION OF THE BRITISH PHARMACOPŒIA.—(*Concluded.*)

By W. Handsel Griffiths, Ph.D., L.R.C.P.E.,

Assistant-Librarian Royal College of Surgeons in Ireland.

ABSTRACT OF THE PROCESSES DIRECTED FOR THE PREPARATION OF THE ALKALOIDS, &c.

ACONITIA.

1.—Digest the root with rectified spirit to exhaust it of the aconitate of aconitia and resinous matter, and then recover the spirit by distillation and evaporation.

2.—Dissolve the alkaloidal salt in water, by which means it is separated from the resinous matter.

3.—Add ammonia to the aqueous solution of the aconitate of aconitia; aconitia and some colouring matter are thus precipitated while aconitate of ammonia is formed and remains in solution.

4.—Dissolve the precipitated aconitia by ether which is afterwards recovered by distillation.

5.—Add sulphuric acid to form sulphate of aconitia, and decompose this subsequently by solution of ammonia, aconitia is thus precipitated while sulphate of ammonia remains in solution.

6.—Wash the aconitia so obtained with cold water, and, finally, dry between the folds of blotting-paper.

ATROPIA.

1.—Digest the root with rectified spirit to exhaust it of the malate of atropia.

2.—By the addition of lime malate of lime is formed, and atropia set free.

3.—Add sulphuric acid to form sulphate of atropia.

4.—Separate any resinous matter which may be present by the addition of carbonate of potash in quantity sufficient to produce neutralisation; remove the resinous matter so precipitated by filtration.

5.—Again add carbonate of potash, but in sufficient quantity to produce alkalinity; sulphate of potash is thus formed and atropia is set free and removed by chloroform.

6.—Distil off the chloroform, and purify the atropia by solution in spirit, digestion with animal charcoal, filtration and evaporation.

ATROPIÆ SULPHAS.

Prepared by the action of sulphuric acid on atropia.

BEBERIÆ SULPHAS.

1.—Exhaust the bark by sulphuric acid.

2.—Concentrate the liquor, and add sufficient lime to precipitate the colouring and vegetable matter, which remove by filtration.

3.—Add solution of ammonia to the filtrate, by which means sulphate of ammonia is formed and the beberia is precipitated.

4.—Dissolve out the beberia by spirit which is to be recovered by distillation.

5.—Again add sulphuric acid to form sulphate of beberia.

6.—The sulphate of beberia so obtained is evaporated to dryness, powdered, dissolved in water, and the aqueous solution is reduced to a syrupy consistence by evaporation, and finally dried in thin layers on glass plates.

DIGITALINUM.

1.—Exhaust the leaves of the digitalinum with rectified spirit, which also takes up colouring matter and extractive.

2.—Recover the spirit by distillation and treat the extract with water, charcoal, and acetic acid; the charcoal being used to decolourise the digitalinum which is dissolved by the acetic acid.

3—Add ammonia to set free the digitalinum from the acetic acid and then precipitate it by tannic acid.

4.—Add oxide of lead by which means tannate of lead is formed and digitalinum again set free, and dissolved in spirit.

5.—Again decolourize with animal charcoal, filter to remove the tannate of lead and charcoal, and again recover the spirit by distillation.

6.—Finally wash with ether to remove impurities.

MORPHIÆ HYDROCHLORAS.

1.—Digest opium in water, which dissolves out the meconate and sulphate of morphia and some codeia.

2.—Add chloride of calcium, to form meconate and sulphate of lime, which are precipitated, and hydrochlorate of morphia, which is held in solution.

3. Evaporate to form a solid mass, and then dissolve out the hydrochlorate of morphia with water. Repeat this process several times, using powerful pressure each time to get rid of the colouring matter, and decolourizing also with animal charcoal.

4.—Add ammonia, by which means morphia is precipitated and separated from any codeia which may be present.

5.—Treat the morphia with hydrochloric acid to form hydrochlorate of morphia which is allowed to crystallise out.

MORPHIÆ ACETAS.

1.—Decompose hydrochlorate of morphia by ammonia.

2.—Treat the morphia so precipitated with acetic acid to form acetate of morphia, which is obtained as a dry powder by evaporation and drying with a gentle heat.

QUINIÆ SULPHAS.

1.—Exhaust the bark of its alkaloids by hydrochloric acid.

2.—Precipitate the alkaloids by adding soda, chloride of sodium being formed and remaining in solution.

3.—Add sulphuric acid to the precipitate to form sulphate of quinia and of cinchona.

4.—Set aside to crystallise. The sulphate of quinia separates first.

SANTONINUM.

1.—Boil bruised santonica with lime and water to form santonate of lime.

2.—Precipitate the santoninum by the action of hydrochloric acid, chloride of lime is thus formed which is held in solution.

3.—Skim off the oily matter and decant the fluid from the precipitate.

4.—Wash the precipitate with water and with ammonia to free it from acid.

5.—Decolourize by animal charcoal and then dissolve out the santonin by boiling spirit.

6.—Set aside to crystallise in the dark and preserve in bottles protected from the light, lest the crystals should become yellow-coloured.

STRYCHNIA.

1.—Exhaust the seeds, by digestion in alcohol and water, of the igasurates of strychnia and brucia.

2.— Add acetate of lead to form acetates of strychnia and brucia, igasurate of lead being precipitated.

3.—Add ammonia to precipitate the alkaloids, acetate of ammonia being formed and held in solution.

4.—Dissolve the precipitated alkaloids in spirit and evaporate the spirituous solution to deposit the strychnia, which separates first, brucia remaining in solution.

5.—Wash the strychnia thus obtained until the washings no longer become red with nitric acid, showing the absence of brucia.

6.—Dissolve finally in boiling water and crystallise.

VERATRIA.

1.—Exhaust the ground seeds (separated from the capsules by a preliminary process) with rectified spirit to dissolve out the veratria together with gallic acid and resinous matter.

2.—Concentrate the solution and pour it into water to precipitate the resin, which is removed by filtration.

3.—Add ammonia by which means the impure veratria is precipitated which the gallic acid unites with the ammonia.

4.—Wash the precipitated veratria with water on a filter, add hydrochloric acid to it to form hydrochlorate of veratria, and decolourize this with animal charcoal.

5.—Add ammonia again by which means the hydrochlorate of veratria is decomposed, the veratria is precipitated, and hydrochlorate of ammonia formed and held in solution.

6.—The precipitated veratria is washed until the washings cease to give a white precipitate on adding nitrate of silver acidulated with nitric acid showing perfect freedom from hydrochlorate of ammonia.

◆

Treatment of Strychnia Poisoning.

In the *Pacific Medical and Surgical Journal*, we find that cases of poisoning by strychnia have been most successfully treated by combination of hydrate of chloral and bromide of potass. It has been suggested, in a communication to the French Academy, that the subject requires further experiment before a definite opinion can be found as to the real therapeutic effects of the compound as the absolute toxic minimum of strychnia is not yet decided.

REGISTERED FOR TRANSMISSION ABROAD.

THE
MEDICAL PRESS AND CIRCULAR
s published simultaneously in London, Dublin, and Edinburgh, every Wednesday morning. Price 5d. Post free, 5½d.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6
" IF PAID IN ADVANCE 1 0 0

⁂ Post-office Orders and Cheques to be drawn in favour of—

A. A. TINDALL, 20, King William Street, Strand, London, W.C.

A. H. JACOB, 23 Ely Place, Dublin.

MACLACHLAN and STEWART, South Bridge, Edinburgh.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIERE, Publishers to the Academie de Médicine, Paris—post free in advance, £1 6s. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLMER and ROGERS; Baltimore, by Messrs. KELLY and PIET; Philadelphia, by Messrs. LIPPINCOTT and Co., and DR. BUTLER, post free in advance, £1 6s., about six and a-half dollars; or direct from the Offices in this country for the same amount, by the new Post-office Order system.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 19, 1873.

UNIVERSITIES AND THE PROFESSION.

DR. LYON PLAYFAIR has adroitly availed himself of an opportunity afforded him by the St. Andrew's Graduates to deliver a philippic against some of their chief tenets, and to read them an indictment against the "one-portal" system. His address abounds with so many things that we might accept, mingled with so many others that we repudiate, that we shall lay before our readers a few of his points assured that they will prove interesting at a time when University Education is being everywhere debated. At the same time we utter a distinct warning that his views cannot fail grievously to disappoint his Medical constituents.

Dr. Playfair denies that the success of colleges should be measured by the number of students who pass through the curriculum of the Faculty of Arts, and thinks those who put this test do so in total ignorance of the origin of Universities, and of their duties as instructors of all who have occasion for learning, and not merely of the wealthier classes. The older Universities, says Dr. Playfair, did not spring from Kings or Popes, but had their origin deep down among the professional classes. The latter wished to glorify their professions by raising them above mere empiricisim. At first they were mere schools, which slowly developed into an academical form; it was not till the 12th or 13th centuries that they assumed their present University state. In support of this view, Dr. Playfair cites the history of Salerno, of the Universities of Paris, of St. Andrew's, Bologna, &c. The Roman Emperor claimed a sort of *veto* over the graduates of Salerno and Naples, and this practice is identical in theory with the *Staats Examen.* of the German States. But both are declared by Dr. Playfair to be radically different from the "one-portal" system which has been advocated in this country. We may admit that it was only after Universities had grown into importance that Popes or Kings threw the mantles of church or state over them; but they did not attempt to lessen their position as places for professional training. Ultimately, professional teaching at Oxford and Cambridge became subordinate to teaching in Arts, which is now looked on as the end instead of as the beginning of University life. This, argues Dr. Playfair, is a peculiarity confined to the English Universities, which, he says, have almost wholly let slip the main object for which Universities were founded—to liberalize the professions—while instruction in arts has become their chief end. Hence, also, they lost their hold on the people, as a whole, and became the Universities of the rich. But the power of liberalizing the professions should distinguish them more than anything else from mere technical schools. The importance of infusing liberal culture into medicine has never been lost sight of; and our Medical legislators have within the last few years insisted on a preliminary examination of Medical students. In Dublin University an M.D. must be a graduate in Arts, but in the Queen's University and in the Scotch Universities this is not the case. Dr. Playfair, however, did not give as much credit as is due in this respect, and glad shonld we be could more still be claimed.

It is nevertheless strange for an ex-professor to [illegible] against classics as we find him doing thus: "Our Latin and Greek education still goes on, though for its practical uses, it is as much a survival as the two buttons behind our coats are survivals of the time when the slits and flaps of our ancestral coats had to be buttoned away. Their existence survives their utility. I look in vain for a single representative man among our Telfords, Watts, Stephensons, Arkwrights, Wedgwoods, whose intellect was nurtured on ancient classical learning, or who could find anything in school life to aid the development of their genius. I look in vain among our scientific heroes—among our Newtons, Daltons, Youngs, Davys, Brewsters, Faradays—for one who owed the cultivation of his intellect to classical education, or did not push aside the school learning afforded to him, as a heavy weight on his mental development. I turn to our Medical discoverers, who were obliged to take a classical education, and how difficult do we find it to select one with even a respectable knowledge of classics. Harvey was a B.A., but among our Jenners, Hunters, Cullens, and Bells, I do not recollect another instance. And yet Mr. Gladstone and Mr. Bruce tell us that old classical system is that which is best fitted for mental culture under all conditions."

Really here we are entitled to express amazement that anyone pretending to speak on such a point should absolutely ignore the chief facts of Medical history. He might, at least, have remembered that the father of English medicine wrote in Latin, and in a style that the first scholars have held to be classical. If Sydenham be thus ignored, it is tolerably clear that we need hardly exp the other early Medical worthies to have been heard Such historical blundering as this only shows the w gulph that separates Dr. Playfair from the Medical P fession. He is more tolerable when he puts forward notion.

The fact is, that all professions have reached a st when a single curriculum for an Arts Degree is no lon possible, if Universities intend to maintain their ch function of liberalizing the professions. It is true th

Universities, which still give prominence to professional degrees, have a poor out-come of graduates in Arts. In the Irish Universities there is one degree in Arts to every six students; in Scotland only one to thirty; and in the London University there is one to twenty-four. Professional training begins at eighteen years of age, before an Arts Degree is attainable. Though society refuses to adapt itself to the ancient liberal curriculum of a University, is it, he asks, unreasonable to expect that the latter should adapt itself to society? We feel that Universities cannot accomplish this by simply adding their subjects to an overloaded curriculum, for in this way, study in Arts, and the requirements of an active profession, ever developing by discoveries in science, can never be made compatible.

The remedy proposed by Dr. Playfair is for the curriculum not to be uniform for all professions, but made to adjust itself to their several requirements. The demand for such a change has resulted from three main causes:— The rapid advance of science, and its numerous applications to industrial life; the free and constant intercommunication of peoples; and the liberalization of political institutions. In the active competition of the world, men cannot afford to spend their life, up to 21 or 22 years of age, in the study of a preparatory degree, which is to be the mere foundation stone of their professional edifice, and Dr. Playfair thinks the difficulty might be met by making the M.A. degree a real step only attainable by a high educational standard; while the lower degree of bachelor, the *bas chevalier* or inferior knight, ought to be reached not by one road only, but by various converging roads suitable to the varying kinds of knowledge required by various professions. At present, clergymen, lawyers, and doctors, as well as men of other professions, struggle to get some sort of literary culture apart from the Universities. Now, few will doubt that a curriculum might be made specially suitable for Medical men, and if this idea were fairly worked out, all graduates in medicine might be required to take the preliminary degree. This is the most practical notion of Dr. Playfair's elaborate address.

◆

THE IRISH UNIVERSITY QUESTION IN ITS RELATION TO MEDICAL EDUCATION.

Neither the speech of Mr. Gladstone nor the Bill which has followed the announcement of his policy, have afforded us any information as to his intentions in regard to the Medical Faculty of the New University, or the medico-educational arrangements of Ireland. The Bill makes no provision whatever for the Medical arrangements of the University, and we must therefore, assume that it is intended that these will be the subject either of amendments and additions when the Bill is in committee—if it ever reaches that stage—or of a supplementary Bill which will be introduced next year, in case the principle of educational legislation on Mr. Gladstone's plan shall be adopted.

It is possible, but not likely, that the Government may choose to confine its attention, for the present, to the Medical Faculty of the New University, and not to interfere in any way with the existing examinational arrangements of the Colleges of Physicians and Surgeons, thus postponing the question of a Conjoint Examining Board for Ireland, until such time as it may be dealt with by the Medical Council, or Mr. Forster, as a part of the coming scheme for medico-educational reform throughout the kingdom. Even in this case the University Bill will exercise an important influence on Irish Medical education and qualification, for it will sweep away the separate licensing function of the Queen's University, and will abolish for ever the £5 Doctorate in Medicine of that Institution, and will thus concentrate in the Royal Colleges of Surgeons and Physicians, the whole extra-academic licensing practitioners in Ireland.

We are, however, as we have said, aware that the Government has contemplated the possibility and propriety of dealing—in this Bill—with the whole Medical system in Ireland, and have had under their consideration the Irish Conjoint scheme, which has been adopted at the conferences of Licensing Bodies held last year, and which will be submitted to the Medical Council at its meeting next month. Before that time comes, the fate of the Bill and of the Government will, probably, have been decided, and if they shall have overcome the difficulty, it may be in condition to give some attention either to the erection of a comprehensive Conjoint Examination and uniform qualification for Ireland, or to the reform of the entire system throughout the Empire.

◆

Notes on Current Topics.

Dublin Obstetrical Society.

We omit publication of the abstract of the communication made by Dr. Kidd to the society at its last meeting, which we had intended publishing in continuation of the report of proceedings which appeared in our last. Dr. Kidd omitted to supply our reporter with the *résumé* of his observations which he had promised, and we object to adopt the alternative suggested by him of copying his remarks from another periodical.

Tracheotomy by the Galvano-Cautery.

La France Medicale mentions the operation of tracheotomy as successfully performed by the galvano-cautery on a boy, æt. 13, who had a little pebble in the trachea for upwards of a month. The operation was thus performed by M. Amusat—a strongly curved needle was introduced through the tracheal tissue, comprising part of the windpipe itself, this needle was furnished with a stout double thread of platinum. When the needle had been passed through, the two ends of the thread were joined by being seized in a forceps which was in connection with a galvanic pile, and the section was performed by the heated wire without the loss of any blood. The trachea was thus opened, and directly the foreign body was forcibly expelled by an excess of coughing. Since this occasion the operation has been performed frequently, viz., five times by M. Verneuil, once by Prof. Voltolini, once by M. E. Bourdon. The *modus faciendi* however of M. Verneuil is somewhat different—he divides the operation into three stages, and proceeds from without inwards. 1st. He divides the skin and soft parts; 2nd. The trachea; the 3rd stage is the introduction of the canula, the precaution chiefly to be taken being that of not injuring the posterior wall of the trachea by too hastily or too deeply entering the tube itself with the galvano-cautery.

Hospital Charity.

The munificence displayed by Englishmen in the support of their hospitals and public institutions, cannot be too highly admired. No doubt in Ireland we have not the numerous merchant princes and others, who can afford large sums, yet, if we could but adapt a system or a conjoint method in the collection of our charities, something might be done worthy of us. Thus, we find that at Sheffield, Hospital Sunday produced £1,443 as collections; at Preston, it produced £329; at Manchester the amount of the collections made last Sunday is not definitely known, but it is tolerably certain that we shall by no means reach the splendid sum of £8,000, which was the result of Hospital Sunday in Liverpool. The largest single collection was made in the Unitarian Chapel in Cross Street, where £216 were subscribed, while they only collected £153 at the Cathedral; but the Unitarians of Manchester are proverbially rich and proverbially liberal.

There is no end, indeed, to the munificence of the Manchester merchant princes and princesses; for last week Mrs. Linchay, in a gift of £200 to the Royal Eye Hospital, added another to the long list of benefactions made by ladies to our Medical charities. Mr. J. G. Frost also presented £1,000, and the late Alderman Rumsey £100 to the funds of the same institution; this long list of donations being crowned by the magnificent bequest of £5,000 made by Mr. James Hatton to the income of the Royal Infirmary.

Such results should encourage us to adopt a harmonious action. What shall we say to such an unostentatious donation as this: that on Tuesday a gentleman called at St. Peter's Hospital for Stone, Berners Street, and left with the Secretary an anonymous donation of the sum of ten thousand pounds, in ten notes of one thousand pounds each.

Self-Mutilation.

The immunity from pain which may be obtained by maniacal excitement, or intense pre-occupation of mind, is remarkably illustrated by the recent case of Mr. March, late curate of Melton Mowbray, who, while residing at a friend's house, besought his host one morning to take out his right eye. That gentleman, on going to him, found he had cut off his right hand, and was in the act of injuring his right eye. Medical assistance was obtained, and the arm amputated, Mr. March remaining quite calm during the operation, and complimenting the surgeons on their skill. Beside him on a table he had a Prayer-book and Bible, the latter open at the passage, "If thy right hand offend thee, cut it off."

Dr. Browne, some time Commissioner in Lunacy for Scotland, in an able lecture on the exemption enjoyed by certain lunatics from pain, mentions that one of his own patients got up out of bed, "and, with a broken chip of his night-vase, cut off his genital organs, and thought it a capital joke!"

During the past Session a somewhat similar case of self-mutilation was brought before the Surgical Society of Ireland, the entire genitals having been self-ablated. We have seen a maniac put his finger into the fire to light his pipe with it, and witnessed the *post-mortem* on a maniacal patient who introduced a chisel up the rectum, and divided the large arteries, no pain was apparently felt by these demented people. The complete anæsthesia during the subsequent completion of the operation on Mr. March, when the intensity of the religious fervour might be assumed to have passed, is remarkable.

Extension of Provident Dispensaries.

We hear that the Committee of the Farringdon General Dispensary has held a sub-committee to examine the question of converting that institution into a Provident Dispensary. The result is that the sub-committee has recommended that the Dispensary be partially altered into a Provident Institution.

Medical Society of Dublin.

On Wednesday last the usual monthly meeting of the Medical Society of the College of Physicians was held at the College in Kildare Street, when Dr. Henry Kennedy read a paper entitled "Remarks on the Etiology of Enteric Fever." A full report of the paper and the discussion on it will appear in our next impression.

Decimation of France by the War.

Baron Charles Dupin laid, on the 6th of January, a statement before the Paris Academy of Sciences in which he sums up the loss of population which France has sustained by the late war. In 1866 he said the population was a little over 38,000,000 and the increase under ordinary circumstances would since then have raised the number to very nearly 39,000,000. It appears, however, from the latest calculations that the country only now contains 36,102,000, which shows a decrease of 2,900,000. Of this number more than a million and a half have been lost by the cession of Alsace and Lorraine, leaving still nearly 1,300,000 lives, the loss of which can only be accounted for, as Baron Dupin says, by the double war of enemies without and within, slain or dead, of misery, suffering or epidemics.

State of the Liver during Lactation.

M. Claude Bernard recently presented to the Paris Academy of Sciences a note by M. Sinéty on this subject. The conclusions arrived at were as follows:—

1. That there is a fatty state of the liver, independent of gestation which is developed at the same time as the function of lactation, continues through all its duration and finishes with it.

2. That the situation of the fat in the lobule is completely different from that which we observe in all other fatty conditions of the liver, infiltration, degeneration, or artificial fattening.

The Prophylaxis of Venereal Diseases.

A recent number of the *Bordeaux Médical*, contains some important observations regarding venereal diseases, and their general prophylaxis, of which we give the most important. They emanate from the Bureau des Mœurs:—

1. The annual number attacked by venereal disease at Bordeaux, is about 2 per cent. of the population.

2. This number does not tend to increase, which constitutes a real improvement in the sanitary state of the city as the population does increase.

3. The sudden increase which occurs temporarily in the number attacked, is due to movements of the floating popu-

lation, such as fairs, political events, changes of garrison, &c., but the duration is brief, and the average is soon re-established.

4. Prostitution is the chief cause of the propagation of venereal disease.

5. Legalised (*tolérée*), prostitution is much less dangerous than clandestine, both in a sanitary and moral aspect.

6. Among the registered prostitutes, those who live in one house, under the charge of a *matrone*, are less dangerous than the isolated ones (*filles en carte*).

7. The private (non-registered) prostitutes are attacked much oftener, and much more severely than the registered.

8. Hence registration is a sanitary measure of the highest importance, and ought to be as widely extended as possible, as it constitutes the best of all preservatives against venereal infection.

The following measures are recommended as most likely to be successful:—

1. Registration of every woman convicted of habitual immorality, and absolutely impenitent, of whatever age, who has no one responsible for her.

2. Abolition of all severe regulations relative to registered prostitutes, because their effect is to make registration objectionable.

3. Special legislation for prostitutes is unnecessary, as their conduct as affecting others is alone affected by these regulations.

4. Careful observance of the only effectual obligation, viz., their inspection, and their treatment until complete recovery.

It is also urged "in the interests of morality and health," that charitable associations should not refuse their assistance to persons affected with venereal disease. Attention is drawn to the necessity for suitable hospital accommodation, both special and in the ordinary hospitals, which it is urged should receive those affected with venereal, as well as with other diseases.

Gonorrhœal Ophthalmia.

The *France Médicale* reports a case of gonorrhœal ophthalmia, under the care of M. Richet, in the Hotel Dieu Paris. Both eyes were simultaneously and severely attacked, and the pain was excruciating, and accompanied by a notable increase in the size of the eyeballs. Ordinary means having failed to alleviate the pain, M. Richet made an incision to diminish the intra-ocular pressure. He made it so as to affect at the same time the cornea, sclerotic and ciliary circle, incising to the extent of nearly five lines. The left eye, which was the worst, was the one operated on. The aqueous humour escaped through the opening, and a small portion of the vitreous. The results were immediate diminution of the pain, and at the end of three weeks, a much greater improvement in the functional and general state of the eye, than was observable in the right one. A scarcely visible cicatrix united the divided tissues.

Transfusion.

The Committee appointed to investigate this subject, by the Obstetrical Society of London, has adopted the following programme of its aims and objects:—

1. To collect evidence from gentlemen who have had experience in cases of transfusion.

2. To obtain the particulars of all recorded cases (performed on the human subject), with the view of finding out, as far as possible, to what extent the so-called successful cases were due to transfusion.

3. To examine the various kinds of instruments used in both the *mediate* and *immediate* forms of the operation.

4. If considered necessary, to institute further experiments for the purpose of determining how far transfusion may be relied upon as a means of saving life, and also the best mode of performing the operation.

We would suggest that those gentlemen who have performed transfusion should take the opportunity of adding such information as they possess to the general stock. They may address the honorary secretary of the committee, Dr. Madge, at the Society's library.

Biliary and Pancreatic Secretions.

The following conclusions arrived at from a series of experiments by M. Defresne were recently communicated by M. Claude Bernard to the French Academy of Sciences:—

1. Bile, in virtue of its alkalinity, plays an important part in pancreatic digestion which, without such alkalinity would be retarded.

2. Bile forms an emulsion with fatty bodies by the help of a special organic acid which only acts when it is in the free state, but any acid can set it at liberty, and such agent is always met with in the entire length of the small intestine.

3. The fat thus emulsed remains neutral and is not modified.

4. The pancreatic sugar causes the most diverse forms of albumen to be converted into an albuminoid which is incoagulable by heat. Starch by its action is transformed into glucose, and fatty bodies are decomposed into glycerine and fatty acids.

The Lettsomian Lectures.

Mr. Henry Lee delivered the third and last of these lectures on the 3rd inst. He gave a very interesting and instructive opinion upon the action of the different striped and non-striped muscles during connection, especially referring to the accelerator urinæ and the non-striped muscular fibres, in the corpora cavernosa; he considered that paralysis of these muscles produces impotence, and that the seminal fluid is poured out into the bulbous portion of the urethra and from thence ejected. The lecturer mentioned a condition, which he had noticed chiefly in women, in which there is an excitement of the generative organs, perhaps three or four times in the twenty-four hours, coming on without any mental or physical cause on the part of the individual, and terminating in paralysis of the organs and dislike for the opposite sex. The experiments of M. Ricord were related, showing that urethral discharges were cured by copaiba, only by the contact of the urine, during its administration. The lecturer considered the balsam of little use as a local application, and also that it should not be given internally, for long at a time, as this drug, like the turpentines, threw extra work on the kidneys and might lay the foundation for disease in those important organs; he generally prescribed it, in combination with sulphuric acid, and continued its use only a week. He had observed that if a syphilitic patient suffered from stricture of the urethra, the malady often required constitutional treatment; and in referring to the calomel bath said, that when unpleasant symptoms occurred, from the irritating quality of the vapour, it was from the presence of impurities (hydrochloric acid), and advised resublimation of the calomel.

Mr. Henry Lee concluded his lectures as follows :—

"We have now considered the principal forms of urethral discharges as they occur in men, and the catalogue is by no means exhausted. Most of these discharges may be communicated in kind to women. A pus-globule, from whatever source derived, will grow, subdivide, and multiply for a time when translated to another part, and may there produce an action of the same nature as that which originally produced it. Some of these actions have a specific character, but many of them have no specific origin.

"In women the mucous lining of the urethra and vagina form one continuous membrane, and the diseases of one part by continuity of action are readily transmitted to any other part. This membrane, taken as a whole, is much more extensive, much more vascular, and therefore subject to a much greater variety of constitutional influences, than the mucous membrane of the urethra in men.

"Any general disturbance of the health will produce a vaginal discharge in women; and these are so numerous that I will not attempt to enumerate them. If, then, the exact nature of a discharge in a man may prove of difficult diagnosis, the difficulty in women is increased tenfold. Hunter, we have seen, did not distinguish between an ordinary gonorrhœa and a syphilitic discharge from the urethra in men; and Babington says, 'the distinction between venereal gonorrhœas and simple purulent discharges which are not derived from infection is to be found less in the severity of the symptoms than in their obstinacy.' The urethra is often attacked with inflammation as violent as that of a gonorrhœa in cases where there has been no possibility of infection. This discharge may be as copious, and exactly similar both in colour and appearance. If this be the case in men, what shall we say with regard to the diagnosis of these causes in women, when we consider the great variety of causes which may give rise to discharges in them, the difficulty there may be in making an examination, and the possible motives for deception? As patients present themselves at the hospital, the diagnosis is sufficiently easy. In fact, they have already diagnosed their own cases, and come ready to mention their symptoms. But the case would be very different if the surgeon had to decide upon his own responsibility, especially if the patient were an unwilling witness. Not long ago I saw a patient who had purulent discharge sufficiently abundant, the whole mucous membrane was red and inflamed, and I thought it must be a case of gonorrhæa, although I was prudent enough not to say so. A week after I saw this patient again. The inflammation had all disappeared. The mucous membrane was of its usual colour, and the discharge not more than natural. I reversed my diagnosis and congratulated myself that I had not unjustly accused the patient. On the other hand, it has not unfrequently happened that patients have assured me that they had had the persons from whom they had been infected examined by their own Medical men, and that they were reported free from all disease; and in some cases the Medical men themselves have called upon me and given the same account. Hunter's opinion upon this subject is thoroughly practical and trustworthy. 'The appearance of the parts,' he says, 'often gives us little information, for I have frequently examined the parts of those who confessed all the symptoms, such as increase of discharge, pain in making water, soreness in walking, or when they were touched; yet I could see no difference between these and sound parts. I know of no other way of judging, in cases where there are no symptoms sensible to the person herself, or where the patient has a mind to deny having any uncommon symptoms, but from the circumstances preceding the discharge; a woman may have this species of venereal disease without knowing it herself, or without the surgeon being able to discover it even on inspection.'

"Surely there is matter here for the serious consideration of any Medical man who undertakes to advise H Majesty's ministers on the working of the Contagious D eases Acts; and especially with regard to the exten of those Acts to the civil population.

"It is not my intention or wish in any way to offer opinion here on the propriety or the operation of the A referred to. But as the responsibility of the princip upon which those Acts are framed will be thrown mately upon the Medical profession, and the practi application of those Acts will involve the personal respon bilitly of Medical men, I am somewhat jealous for the futu honour of our profession, and anxious that any opinio and advice given by us to the Legislature should stand t test of time, and, in order that they may do so, that th should be established upon a really scientific basis."

At the close of the lecture the President (Mr. Bryan in thanking Mr. Lee, said, that he had put the treatmen of those diseases upon a scientific basis, which were befo often treated empirically. The address was received wit loud applause.

The St. Andrew's Medical Graduates' Association.

An extra General Session of this Society was held the Freemason's Tavern, Great Queen Street, Linco Inn, under the able Presidency of Dr. Lockhart Robe who also filled the chair at the dinner which follo with his usual geniality and grace. The event of t evening was Dr. Lyon Playfair's address on "Univer as Places of Professional Education." This address, w was received with applause, was an able argument, rather series of arguments, against the "one portal syste which Dr. Playfair considered would be a sure means degrading the Profession. The evening passed off ver pleasantly and nicely, the warmth within compensating fo the cold without,

The London and Dover Female Convalesce Home.

This useful institution has been three years in existenc In the first, 172 invalids, chiefly from London, were rece in it, in the second, 458, and in that, the report of wh has just been published, 568, thus, under the energ management of Mrs. Marshman, its benefits are bei rapidly extended. The classes of women who, during t past year, have been received into the Home are t following, namely :—71 governesses, 28 reduced lad 166 needle-women, 23 matrons, 7 telegraphists, 34 bil women, 36 shopwomen, 72 in domestic employ, and children. All these have been relieved at an expense to funds of the Home of £945 8s., leaving a sum in hand £132 17s. 5d.. It is right to add that T. C. Parsons, Dover, is honorary surgeon to the institution,

The Royal Zoological Society of Ireland

Sometime since the Council of the Royal Zoolog Society of Ireland decided on raising the price of adn sion to their gardens from 6d. to 1s., a resolution wh was much disapproved of by the citizens of *Dublin*. T step seemed, however, to have been justified when it v stated by the Council that it had been attended with t best results, as regards the finances of the Society wi out any commensurate decrease in the number of perso who availed themselves of the advantages of the Socie We find, however, by the Annual Report for 1872 ju issued, that this latter statement is perfectly erroneous, and that the effect of the increased price of admission has been only an insensible increase in the funds, while it has caused the number of visitors to the gardens to fall away to nearly one half what it was.

In 1871 the visitors at 6d. each numbered 30,603. In 1872 only 14,400, and the gross number of visitors was less by 20,000 in 1872 than in 1871. That this falling off was not, as stated in the Report, due principally to the inclemancy of the weather is proved by the fact that the Sunday penny admissions were only about 6 per cent. less than in 1871. The exclusion of these 15,000 visitors has been purchased by an increase of income of barely £150, which surplus may be more justly credited to the smallness of the stock of animals maintained by the Society. The Council has 10 per cent. less animals to show than it had in 1871. We suggest to the administrators of the Society the propriety of retracing their steps.

A French View of American Sham Degrees.

To-day, says the *Bordeaux Médicale*, we find in the pages of a Berlin Medical journal information which proves the danger of absolute freedom in teaching and the necessity of state intervention in the matter of degrees and diplomas. It appears that the illegal distribution of degrees in medicine by some American institutions has made the legislature of Pennsylvania nominate a commission to inquire into the facts. The institutions complained of were the University of Pennsylvania, the Jefferson Medical College, the University of Medicine and Surgery of Philadelphia, and the Eclectic College of Medicine, all of which are in existence in Philadelphia. There is no charge brought against the two first of these bodies, which is not the case with the others. It has been ascertained by the declarations of witnesses that the University of Medicine and Surgery of Philadelphia has made a traffic in the sale of diplomas to persons who had not even followed the courses, and who had received no Medical or scientific instruction. It appears that the director had conferred for the sum of 200 dols., the degree of doctor on a person whose name was totally unknown to him, and who was found to be a child of two years of age. The registers of the institutions prove that many diplomas were thus bartered for money; and the names and indication of the persons who were thus adorned have been ascertained.

At the Eclectic College of Medicine the traffic in diplomas took place publicly and systematically. Thus it is that diplomas, regular in form and signed by the Faculty, had been granted to women who could not even say where the college was situated.

The commission, therefore, has proposed to withdraw from the above-mentioned institutions the rights granted them, and this was unanimously passed by the Legislative Assembly.

"It appears from these facts that in the American Republic, where honest men do not combine to put an end to put an end to abuses, legislators are forced to act; what better argument can we have in favour of Government interference. Whilst we demand, however, State intervention, it must be clearly understood that this should only be in order to watch the delivery of degrees and put a curb on the facilities which certain universities may grant in order to attract to themselves a great number of pupils. We do not desire in any way to put a stop to the liberty of teaching, for in this we demand liberty for all, and that private persons, associations, corporations, and municipalies should have full liberty of creating schools."

The Mrs. Day Fund

The Executive Committee have appointed Dr. Paul, Dr. Lockhart Robertson, and Dr. Sieveking, trustees of this fund, with power to invest the money, and with instructions to pay the interest thereof, as it accrues, to Mrs. Day, and at her death to divide the principal sum between her two daughters.

The subscriptions already received amount to £724 17s. in addition to a widow's grant by the Royal Literary Fund of the sum of £100. The expenses, including postage, printing, and the necessary trust deed, will amount to about £45.

The committee is very anxious to raise the fund to £1,000, in order that a position of permanent, even if very moderate, comfort may be secured to Mrs. Day. The list of subscribers is already a long one, and includes many influential names.

New Books.

The last month has been, as it usually is, somewhat meagre in its book produce, most of the works issued to the Profession being new editions. Of these we have the second issue of Adams on Gout and Rheumatism, with a handsome atlas of plates, which is in the hands of our Reviewer. In addition, the following have been published:—Chavasse's Advice to a Wife, 10th edition; Tilbury Fox on Skin Diseases, 3rd edition.

Berkeley Hill's Essentials of Bandaging, 2nd edition. More Madden on Change of Climate, 2nd edition; and the 8th edition of Watts's pamphlet on Inhalation for Lung Diseases. Of new books we have only G. Herbert Morell's Student's Manual of Comparative Anatomy, part 2. *Aves.* Paskin's Epidemiology, part 1.; Paton on the Action and Sounds of the Heart, and a pamphlet by Mr. Dyke on the Work of a Medical Officer of Health.

For the coming month, Messrs. Longmans announce the first volume of Budd on Typhoid Fever; Messrs. Smith Elder will issue a manual of Public Medicine, edited by Mr. Ernest Hart; and Messrs. Bailliere, Tindall, and Cox, Inspector-General Dr. Gordon's work on Hygiene and Military Surgery.

We note also the issue of the following additions to scientific literature:—

Bell (Robert) Biogenesis, as Exhibited in Decomposition, and Putrefaction, 8vo, pp. 28.

Fox (Cornelius B.) Ozone and Antozone; with nine lithographs, 8vo, pp. 346.

Lees (William) Elements of Acoustics, Light, and Heat, 8vo, pp. 140.

Thomson (Sir William) Papers on Electrostatics and Magnetism. 8vo, pp. 592.

The following are announced for the coming month:—

Text-Book of Botany for the use of Students, by Robert Brown, M.A.

The Æreal World, by Dr. George Hartwig, 1. vol. 8vo,

Popular Lectures on Scientific Subjects, by H. Helmholtz 8vo.

Illustrations of the Power of Speech in Persons said to have been Deprived of their Tongues, with Special Reference to the African Confessors, by the Hon. Ed. Twisleton, 8vo.

M. **Jungfleisch** has succeeded in preparing tartaric acid, by complete synthesis, from artificial succinic acid obtained from bromide of ethylene.

The deaths from cholera in the army in the Bengal Presidency during the past year was 562, more than 50 per cent. of the seizures.

Injections of arsenical solutions in the form of Fowler's solution, have been used by M. Eulenburg, for the cure of psoriasis, paralysis agitans, and other affections; the irritability of stomach, sometimes consequent on arsenical administration, being thus avoided.

When we hear so much of deaths by furious driving, and the dangers of the road, the statistics of accidents in Paris show an alarming ratio. There are 1,200 omnibuses, 8,000 private carriages, 10,000 carriages on hire, 25,000 vehichles for transport of goods. These various vehicles in Paris during the year killed 135 persons and injured 1,200. As the population is about two millions, the proportion is considerable.

In a recent meeting of the Medical Society Mr. Carter called attention to Dr. Bell Taylor's (of Nottingham) operation for cataract as being the best operation among the three or four recently proposed. There seems to be some difficulty as to the steps of this operation, which perhaps its inventor may some day give an explanation of in the form of a diagram.

The results of a series of experiments made by M. Duquesnel, on the injurious effects of iodine, pure and dilute, on vulcanised india-rubber, are briefly summed up in the *Bordeaux Médical*. These effects are stated to be due to the sulphur, and non-vulcanised india-rubber is recommended.

Correspondence.

THE IMMEDIATE CAUSE OF NAPOLEON'S DEATH.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The sudden and unexpected death of the Emperor Napoleon III. has created such an amount of sensation and speculation as to its *immediate cause*, that amidst the diversity of opinions no solution sufficiently satisfactory to scientific or public inquiries appears to have been given. Some have endeavoured to account for it by the effects of the operation of "lithotrity," acting severely on an impaired constitution; notwithstanding that, on an average calculation, the mortality in such cases does not exceed more than 4 per cent.; others attribute it to poisoning by retention of urea, though it looks rather strange that that agent should not have manifested that *particular effect* previously to that occasion, which would not be at all surprising; others again ascribe it in no small degree to exhaustion, consequent on the want of an adequate supply of nutriment and too low a regimen; and so forth,—all which attempts at explanation seem to me not to be founded on the knowledge of the truth. Accordingly, curiosity has led me to investigate the various circumstances and bearings of the question, and I have been at length induced to arrive at the conclusion that the *unforeseen changes* which took place in the Emperor's condition at the hour of dissolution, are traceable in a great measure to the depressing influences and effects of chloroform, combined with those of that "powerful narcotic draught," which, as reports state, it was deemed advisable to administer to him the night preceding "*his last long sleep*."

The *post-mortem* examination revealed an advanced varied, disorganised state of the kidneys, with which is frequently associated cardiac disease in some form or other, as well as atheromatous degeneration, and anæmia. Even when the former lesions are absent, there is, for the most part, a strong tendency to the development of the latter, as the richest constituents of the blood are apt to be impoverished, owing, among other reasons to depuration; and hence, it often occurs that the appearance of persons so affected is characterised by a sickly pallor, or other varying hues, modified to some extent by the natural complexion, as well illustrated in certain forms of Bright's and Addison's diseases. The "*vesical calculus*," it seems, consisted mainly of the "amorphous phosphate of lime," incrusted with layers of the "triple phosphate." The researches of Dr. Prout, and other eminent pathologists, would lead to the conclusion that the generality of "calculi" are chiefly formed in the pelves of the kidneys, whence, in their descent into the bladder, they are wont to irritate and dilate the "ureters," but exceptions to this rule arise, and there are not wanting authors of distinction, who maintain that the "phosphate of lime" description usually takes its rise from abnormal secretions of the bladder itself, acting on some *nucleus*, from which a sympathetic irritation propagates its influence upwards through the ureters to the substance of the kidneys, thereby causing occasionally serious mischief. Be that as it may, it has been confirmed by the authority of several great surgeons of experience, including Sir B. Brodie, that when any of the "*triple phosphates*" are deposited, the general condition of the constitution, which leads to the secretion of alkaline fluids in excess, is mostly attended with a peculiar morbid sensibility of the nerves, which cannot fail to exercise a deteriorating power over the digestive functions, the assimilative, and the normal physiological transformations of the *chylopoietic materials*. Under such diseased conditions the blood itself cannot retain its natural amount of chemical consistency, and richness in hæmatine particularly, hence, a state of anæmia will often ensue, varying in results in different individuals.

Without dilating, however, on the various causes, that would predispose to, even lead to the above species of anæmia, either directly or indirectly, the force of analogy coupled with other circumstances, induces me to believe that not only did an anæmic condition of the system prevail for some time, but also that it acted as a serious complication during the last illness of the Emperor Napoleon. The foregoing inferences are also confirmed by deductions from the descriptions given of him occasionally by several acute observers of "men and things," who had opportunities of *interviewing* him closely in latter days; and it is not unworthy of note that, according to reliable information furnished by the Paris correspondent of the *Irish Times*, marks of incipient decomposition of the body were curiously observable before interment, notwithstanding the conservative process of embalming. That the administration of *chloroform* as an anæsthetic is often a perilous and deadly agent, experience teaches from the numerous fatalities that have been from time to time witnessed and recorded. That it even ordinarily exercises a powerful depressing influence over the action of the heart and the circulatory fluid, is a fact, in confirmation of which innumerable testimonies might be adduced. One remarkable proof can be drawn from the circumstances that, after amputations of the limbs, the blood that may flow from divided vessels is wont to be attended with a feeble force, and dark venous-like colour, as contrasted with the strong energy, and bright scarlet complexion, with which it sets forth, after the inhalation of the stimulating properties of *ether*. Again, the effects of chloroform have often been so startling and unexpected in their character, that many Medical men of extensive experience have been obliged candidly to admit that, in the long run, they would shudder at the idea of its application.

During the terrible battles which raged during the great American campaign, chloroform appears to have fallen into considerable disuse and distrust; while, on the other hand, ether was held in great vogue, and employed with confidence and satisfaction. The same practice prevails at the present day, in the vast majority of the chief hospitals of that vast Continent, as well as in other no less enlightened countries. In a learned article which appeared last December, in the *British Medical Journal*, on the dangers liable to arise from chloroform, in one part it arrives at the conclusion that the proportion of fatalities ascribable to the effects of chloroform, as compared with ether, may be estimated at seven to one, on calculations derived from "reliable statistics." If then, under its administration, accidents occur in instances which at first seem to afford no grounds for serious apprehensions, how much more likely are they to take place when the constitution is impaired and debilitated from general and local morbid humours, intensified by prostration of the nervous centres, as well as a deterioration in the normal standard of "red globules," all which more or less conspire to diminish the power of the muscular tissue of the organ of circulation and its concomitants.

What wonder then is it that in some cases characteristic of this kind, chloroform in its effects, as well as a few other particular narcotic substances, should even *paralyse* the motions of the heart itself, and produce *syncope!*

There may be some, however, who would imagine that because no fatal consequences would manifest themselves within a certain period after anæsthesia, it would be unfair to trace them subsequently to that source, but that line of reasoning would be illogical, and contrary to the spirit of the laws of *induction*. The heart, like the brain, may be subjected to severe shocks from various injurious agencies, and though no fatal signs may appear immediately, reaction being feebly established for awhile, still experience shows that more remotely they often are developed with dangerous results. Examples illustrative of this doctrine are best shown in several concussions of the brain and spinal cord. Among the special narcotic drugs, most employed of late, "chloral hydrate" holds a conspicuous place, and though as a soporific agent it is entitled to high repute, still, in certain states of the system, most particularly when anæmia exists to any extent, it is fraught with serious danger, as it also has a tendency to paralyse the heart's action, especially if either fatty degeneration or atrophy may happen to exist. Two cases illustrating its perilous influence have been recorded, not long since, in the *New York Medical Journal*, in which sudden and unexpected death took place, and the conclusion drawn from the *post-mortem* examination, was that death occurred from its paralysing action on the energy of the heart, though there was no morbid lesion discovered, except traces of anæmia in the brain, to the presence of which the weak condition of the vascular organ was chiefly attributed. That some preparations of opium also occasionally exercise a deleterious comatose influence on the system, primarily on the nervous, though secondarily mostly on the sanguiferous, is a fact to expatiate on, the details of which might take up too much of your valuable space at present.

What was the particular composition of the "powerful narcotic draught" that was given in the case of Napoleon, I have not seen specified, but that its influence played no inconsiderable part in hastening on the unexpected sad event, (*quidquid accelerat causat*), several are induced to entertain no reasonable doubt, though other predisposing causes existed. Some profound thinkers may be disposed to cavil at its plausibility, or to question the whole circumstances after the style of the famous disputation about "who killed Cock Robin."

To be brief, having duly pondered on the different aspects of this apparently mysterious business, I am actuated with a strong persuasion, participated in by several physicians and surgeons of eminence, that it is to a great extent due to the combined effects of *chloroform* and the *narcotic draught*, acting conjointly, varying in degrees, both directly and indirectly, that the span of the varied career of that extraordinary personage, Napoleon III., had so soon, and so unexpectedly reached that "bourne whence no traveller returns."

Yours,
William Hegarty, M.D.

Kinsale, February 1st, 1873.

ANEURISM OF THE AORTA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Perhaps the following imperfect statement of a case of aneurism of the aorta, is of interest enough for a place in your columns, if so, I hope you will do me the favour to insert it at your convenience.

Several Medical men now in Belfast, and some now abroad, all of whom I believe read your Journal, have seen the case at various periods, and would, I have no doubt, like to know when, and how, it terminated.

Charles Adair, æt. 44 years, died on the 14th inst., from hæmorrhage from an aneurism extruded from a little above the centre of the sternum. He had left the army twelve years ago. He had served fourteen years in the 6th Infantry, he had been with his regiment in Africa and India. While with his regiment, he had been occasionally in hospital, first for pain and distress in his chest, and afterwards for a tumour projecting through the sternum. He left the army of his own accord and got no pension, and the reason he gave me for leaving, was that he feared the surgeons would operate on the tumour—would remove it. Up to the last, indeed, he had no correct notion of the nature of his disease. On coming home he became a dispensary patient of mine, and I recollect sending him to a meeting of the Clinical and Pathological Society of Belfast, at which he showed his aneurism about twelve years ago. He married eleven years ago, and at the time of his death, his wife had borne him six children, three of whom are living and healthy, and three dead. He supported his wife and family by weaving, and from the time of his marriage to the 23rd of the last month, I believe he had not been one day off work from bad health. He was always temperate since he left the army. He occasionally showed himself to me during the past twelve years; the aneurism had slowly and gradually increased in size, remaining firm up to the 7th instant, when he came to the dispensary with a black ticket, and shocked me by exhibiting the changed state of the tumour. The highest part of it was projecting very much, was quite soft, and was pulsating violently, the skin over it was much stretched, and two spots were black and sloughing. He had walked two miles to the dispensary. I urged him to go into the hospital but he would not. Lint adhesive straps and a bandage were applied, he was told how to dress the place, and was given digitalis and aromatic sulphuric acid; was advised to go to bed and keep as quiet as possible. I heard no more of him until the 14th inst., when I got a ticket to visit him, but before I arrived, he had died of hæmorrhage. Several small bleedings had for twelve hours before, preceded the profuse discharge which killed him. I got leave to lift the sternum, but no satisfactory examination could be made in the circumstances, I merely ascertained that the heart appeared sound, that the aneurism originated about two inches from the pericardium, that the whole breadth of the sternum was occupied by it, that the bony opening was circular with ragged edges, and that it was somewhat funnel shaped, the ribs at the margin projecting outwards. It is well that my patient was not an anatomist or physiologist. His "ignorance was bliss," it gave him the courage to marry, and it prevented the solicitude and mental disquiet a true knowledge of his disease would have caused. His case is a contrast to that of the Italian Student, who, after learning anatomy, feared to take any active exercise, lest he should rupture some of the delicate vital tissues of his organisation. No surgeon in Great Britain, with an aneurism of the aorta the size of an orange protruding through the sternum, would even, at the mature age of thirty-three, have the pluck to venture on matrimony as my patient Adair did. A short time ago, I saw another case just like Adair's in a discharged soldier, also a weaver. He died in hospital of fever, and up to the time of taking fever, he had wrought at his trade. Both men attributed their diseases to the weight they were obliged to carry when marching with their regiments.

I had frequently prescribed digitalis and morphine to Adair for pain in his chest with relief, but I had not seen him for a year previous to the 7th inst. Of course he was always cautioned to abstain from intoxicating drink, from severe exercise and excitement of any kind. He was a thin pale person, but rather muscular. Depletion could not have been borne by him at any time.

David Jamieson, M.D.

Newtownards, 29th January, 1873.

THE LATE MR. BAKER BROWN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Every independent and thoughtful mind in the Profession will rejoice and second your remarks on the unmeaning, ignorant, and purposeless attack on the late Mr. Baker Brown. America and Europe generally bear witness to the vigorous work done by men like Morton or Baker Brown. One, the great pioneer in anæsthetics, the other, on ovariotomy in this country, both crushed by a miserable faction, both brave men who dared to take a great step that no other had taken previously.

Let the quiet observant surgeon read Peaslee on ovariotomy, and a paper by Marion Sims in the leading New York journal just arrived from America, in both of which due honour is given to the late victim of all this small bitterness and obstructiveness. The moral propriety of another operation for relief of that terrible disease epilepsy, was called in question by persons who admitted they had never seen it or the cures effected—peculiar people who would wish for no cure, no relief, if not in accordance with religious precedent. This operation, carefully misrepresented, was made the subterfuge or pretext for an unmanly attack on this surgeon.

How fine is Robert Burns on the rigidly righteous and rigidly wise "counsel for poor mortals," these "peculiar people" who will only do good as a secondary matter to indulging private pique in the first instance.

> "Discount what scant occasion gave,
> That purity ye pride in ;
> And (what's aft mair than a' the cave)
> Your better art of hiding."

One point must still be greatly dark, the motive of all this sanctimonious but illogical yet orthodox surgery.

Yes ! scripture precedent ; who does not look back with shame and remorse at these old scenes, "fantastic tricks at which the angels weep, of a few men dressed in brief authority."

As one who, during twenty years visiting of hospitals, had watched Baker Brown's first ovariotomy down to his last, I think it would be pusillanimous not to say these few words : Persecution has marked his career from his earliest efforts at St. Mary's Hospital down to his latest at the "Home"—the men who talk in libraries who never witnessed his anxieties, gossip and repeat their condemnation of what obviously they never saw. He is now beyond our praise or blame, but the shame and Tartuffe "bosh" remain ; we can no "farther drag his frailties from their dread above." All honour to you and Dr. Forbes Winslow ; but it is a pity to let such folk as those who organised an attack on this hapless surgeon sail off with flying colours ; such proceedings paralyze all intelligent efforts at original researches. We have had enough of such obstructiveness in resection of joints, compression of aneurism, &c. The *Lancet*, now he is dead, admits "that the intention of this man was honest in suggesting this cure for epilepsy."

A word that, as usual, comes too late ; the independent men know it was honest ; the mere time servers are afraid to say so much. Those persons who watched those epileptic cases to the end know that many of them were benefited or cured, not one injured. America will set him right.

REQUIESCAT IN PACE.

London, Feb. 8.

◆

THE PROPOSED NEW CHARITY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—My attention has been called to some letters recently appearing in your columns, signed respectively "A. W.," "M. D.," &c., writen in a rather inflated style, and advocating the claims of a so-called "new charity." I was a little astonished that you should have allowed the unhappy authors to make so painful an exhibition of their ignorance of everything relating to the laws of political economy, such a strange deficiency in the power of forecasting events as is displayed in these letters. Are we to look to the future hoping to level upwards or downwards, to instil into the multitude some portion of self-respect, or to continue our efforts to reduce them all to a state of pauperism, cheap law, free law, certainly let us have it by all means, let us go on till everything is free, and nobody pays anything for anything, but seriously, Sir, is not all this the wildest nonsense ? Because one profession in its mad silly competition is impoverishing, degrading itself, and pauperizing the people, is that any reason why another body of men should do the same. Because "A. W." chooses to spend thousands of his money, and years of his time for the privilege of working for nothing at the end, is that any reason why I, or any sane man, should do the same ? The profession of law, as now conducted, is purer, fairer, and certainly cheaper, in this country, than in any other, its professors are harder worked and less paid than the great bulk of the community, and if they are to proceed a step farther and work for nothing, I would suggest that the colliers, the iron workers, the gas stokers, &c., should follow their example and work for nothing also. Let "A. W." look at home, is it possible that he cannot see how his profession is injuring itself and others ! The tendency of human nature is to value any given person or persons at very much about the valuation they place on themselves, and at what valuation can the advice be rated of any one who, after a long, tedious consultation, hesitates to accept the very small fee tendered ? What are the heads of such a profession about ! To take the case of some celebrated physician in the west, possibly a court physician, and spoken of by the papers as "a distinguished light of a learned profession," now on what terms can his advice be obtained ? why, I believe, for a solitary guinea, a fee so small that the youngest M.D., one who has only just got on to the staff of his hospital, would decline to take less ; now clearly there must be something wrong here, either the junior receives a sum far exceeding the value of his services, or the senior is as ridiculously under-paid, for his, truly to this it could be said that while the juniors fees are few and far between, those of the senior crowd on him in overwhelming numbers, but this is an argument entirely in my favour. Doubtless the junior spends his time chiefly either in unprofitable work or in looking out of the window, wondering how he shall pay his tailor's bill, while the senior is besieged with a crush of material which he lacks the time, the power, and possibly the inclination to do justice to, but to what, Sir, ought such a state of things lead ? not, I should say, to pulling others down to the same level, but to a rational attempt to level upwards, let a senior physician charge something more according to what is or ought to be the value of his advice. Suppose that a few of the heads of the Medical Profession were to expect on a first visit a fee of twenty-five guineas, with a refresher of five or ten guineas on every subsequent occasion, what would be the result. I think a gain in every way. They would have far more leisure, and, I fancy, more money, the junior physicians would be at work at proportionately less fees, while the richer members of the community who, as a rule, would insist on having the best advice, no matter how much they had to pay for it, would really get what they paid for, in the attention of a physician at leisure to go into their cases, instead of the limited number of minutes they are now allowed by the impatient and overworked doctor who hardly conceals his glances at the timepiece, wondering how soon they will pass out and leave him to obtain another hardly earned guinea.

If "A. W.," and others, would turn their attention to their own profession with its ruinous degrading competitions, and petty jealousies, they would cease in the endeavour to reduce a profession already almost as poverty stricken as their own, and would probably be too well busied in more profitable matters, to find time for letters which do as little credit to their common sense as to their powers of English composition.

I have the honour to be, Sir,
Your obedient servant,
A LAW STUDENT.

◆

THE DEATH FROM NITROUS OXIDE AT EXETER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—"Salus populi suprema lex." Such is your motto. Does the occurrence at Exeter illustrate the application of science for good or for evil ? I assume your report of the paper read at the Odontological Society is correct. No doubt it is. What then does it show ? Was the case one of surgery, or merely dentistry ? It would be profanation to call the treatment surgical. Of *true* surgery it is an axiom not to do more than is necessary. The case in question, then, was one of dentistry—*Exeter dentistry*—and must stand on record, by the evidence of its own report, as an example of what *Exeter dentistry* is. As I understand the case from your report, it was simply one of extraction of a tooth, under the influence of nitrous oxide. What could be more simple ? The manipulator—operator, if you please—having given the gas, proceeded "to cut off the crown of the tooth," an act utterly unnecessary ; he could just as well have extracted the tooth entire as to cut off the crown, there was no apparent reason why he should not ; but, having cut off the crown of the tooth under the influence of the gas, he proceeded "to *thrust* a spear-pointed instrument into the pulp cavity," another unnecessary act, and with a *twist*, purposely made, he split the fangs—a third unnecessary act. From this splitting, so much pain was produced that the action of the gas was neutralised, and the ient declared "she could not bear any further operation bout more gas." Up to this time the gas had not produced poisonous action, but just three times as much "operat-" had been done as would have sufficed for the extraction the tooth itself.

he pain, we are told, was caused by the periosteum of the being inflamed. Very likely. But why not the peri- m of the sockets as well? Yet, into the exquisitely itive pulp cavity of the tooth and inflamed periosteum the -pointed instrument was *thrust*, and the fangs broken up a twist whilst the fangs were in the socket. Such is dentistry to a delicate lady! Again, it is perfectly om the operator's own showing in his paper, that up to of cutting off the crown of the tooth sufficient gas given to extinguish pain without any poisonous ing produced. If then, as it ought, the tooth had tracted instead of cut off, the terrible pain from the *of the spear-pointed instrument*" would not have been d, no more gas would have been given, and the poor ould have been alive.

after the second exhibition of gas another scene oc- d. The stumps from which the crown of the tooth had ut had to be extracted. After one failure this was ac- lished. At this stage the symptoms became "alarming." her words, the operator was frightened. "An old atten- ," seemingly the only cool and sensible person present, imed—"Take out the gag, she is choking." This was *ably*" done, for it needed "*great force*" to separate the Yet we are immediately told that between these jaws, required so much "force" to separate them, the careful tor put his finger to press forward the tongue. Happily, aped without amputation of his finger, and was able to way for some one to help him! What an exhibition! a "surgeon" with a patient *in extremis* running after Where was the good, faithful, sensible "old atten- ?" Surely he, *the best man* of the lot, or a servant might gone. The circumstance reminds me of what occurred to myself whilst operating for hernia. I had just raised teguments between finger and thumb, and passed the through, when a professional friend who had promised present perspired very much, and suddenly exclaimed—dear, don't, I cannot stand it." I advised my friend to own, and went on with the operation, and was glad to see my friend recovered, and so did the patient. Better far under such circumstances, the patient should die in a 's hands than that he should leave the post of duty for ent. Imagine a case of hæmorrhage, from whatever and whilst life was oozing a doctor running away for "Of course, no one imputes wilful wrong. All was done best," no doubt. But the case carries our thoughts another subject, and induces us to ask,—What od are *Medical Colleges* and *Corporations*, or that worst imposture, a *Medical Council*, if they cannot something better than the practice in the Exeter case? US POPULI SUPREMA LEX."

I am, Sir, your obedient Servant,
W. HEMPSON DENHAM, M.R.C.S.
outhsea, Portsmouth.

DEATH FROM NITROUS OXIDE GAS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Every professional man will join with you in deprecating the discussion of subjects like the above in the newspapers. Such discussions can have no other tendency than to cause confusion in the minds of the public, who are quite incapable of forming a judgment upon the points at issue. It is difficult to see what good Dr. Chas. Kidd could expect from the letters which he has recently addressed to the *Daily News*. The first of these letters appeared on Jan. 25th, and in it he stated, that not one but four deaths had taken place from the inhalation of nitrous oxide; that chloroform was, on the whole, as safe as any anæsthetic; that chloroform was safer than nitrous oxide; for that under the former the patient might be compared to a ship in troubled waters "with a pilot on board," but under nitrous oxide he was like a ship in the same situation without a pilot. Everyone of these statements was opposed to the truth, and Dr. Kidd, having discovered his mistake, and having found that he could not prove the assertions which he had boldly put forth, set to work to show with his own hand how worthless they really were. To the *British Journal of Dental Science* for February he sent a communication dwelling upon the comparative safety of nitrous oxide. This the editor printed, appending Dr. Kidd's *Daily News*' letter, and remarking upon the singular inconsistency of the views expressed. Next, in the *Daily News* of the 11th instant, Dr. Kidd writes that his "impression" remains unchanged that nitrous oxide is the safest anæsthetic; forgetting that his "impression" had changed within a few days, and not recognising the improbability that "impressions" on matters of Medical science, which vary from day to day, can have no weight with the Profession or with the public. The four deaths he did not attempt to authenticate, and I would remark that they are unknown to those who have been engaged in carefully collecting statistics, and to say the least are questionable. Although the vague assertions which Dr. Kidd put forward could have no value to scientific readers, they have had the effect of alarming nervous patients, and of preventing, in many suitable cases the use of the gas, which in qualified hands is, I venture to say, not only the safest anæsthetic, but almost absolutely safe. This is proved by the unvarying results of experiments upon the lower animals. It is found that when the gas kills, death always commences at the lungs, and that so long as the heart's action continues, the creature recovers (as a rule, spontaneously) on admission of atmospheric air, or aided by artificial respiration. The gas has not, like chloroform, an accumulative poisonous action, and it never kills suddenly by direct action upon the nervous centres. The statistics of chloroform show one death in every 3,000 cases; the statistics of nitrous oxide show one death in several hundred thousand cases. Chloroform has been rarely employed except by well qualified Medical men; nitrous oxide has been given extensively and indiscriminately by large numbers of unskilled practitioners. I must not be understood to imply that because statistics and our knowledge of the physiology of the gas show it to be a safe agent it is therefore one which can be used without damage by the ignorant. The condition of insensibility from an anæsthetic it is probable will never be free from some small danger, either from direct action or intercurrent causes; and in the case of operations in the mouth there is always the risk of foreign bodies being drawn into the larynx. In the event of an accident, the administrator ought to be able to recognise the symptoms, and to act instantly. It is not enough to render the patient insensible, and to trust in every case to an unaided recovery. The Exeter fatality shows that under some circumstances a death may follow the inhalation of the gas in the hands of qualified practitioners. Can those who have a mere knowledge of the physical signs of anæsthesia, who cannot, for instance, distinguish between syncope and apnœa, continue to employ nitrous oxide, and if they do is it uncharitable to hope that on the occurrence of an accident, after the unmistakable warning which they have now received, they may not escape the legal penalties which such temerity will certainly call for?

Your obedient servant,
HENRY SEWILL, M.R.C.S.
6 Wimpole Street, London, W.

THE USE OF ETHER IN OPHTHALMIC SURGERY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have not desired, in my previous letter to you, to imply that the administration of ether by your correspondent Mr. Morgan, of Moorfields, or by Mr. Wilson was unskilfully carried out. I am sure that the admixture of air and ether which was employed by these gentlemen received every fair play at their hands, but I nevertheless consider that they would avoid all the *desagremens* of which they complain if they would exclude the air as much as possible, and administer the agent with an inhaler, the principle of which is such exclusion.

I am not so hasty in my inferences as to assume that undiluted ether vapour is harmless because it has not killed any of my own fifty cases. Since Dr. Morgan perfected his inhaler he has given ether with it in more than 350 cases, and since it has been brought under the notice of the Surgical Society of Ireland it has been used by others in about 100 more.

In not one case, as far as I have heard, have symptoms in the least alarming been developed. It is, however, from study of the effect of the ether on the heart that I form an opinion favourable to its safety, for it seems to me to be conclusively established from sphygmographic and other observations that its effect on the circulation is decidedly stimulant, and I, therefore, entertain no apprehension of the occurrence of the heart paralysis which is said to be the usual cause of death by chloroform.

I do not feel able to discuss the superiority of bichloride of methylene with your correspondent, whose experience of it is very large, while mine is very small, but as he admits that he has been the next thing to "seriously alarmed" by its action, and that he does "not think it absolutely safe," I am not disposed to exchange my confidence in ether for a trial of the new anæsthetic.

While I concur with your correspondent that we cannot, as yet, jump to the conclusion that undiluted ether vapour is absolutely free from danger, I think we may take it as proved that our experience, so far as it goes, and the observed physiological effect of the agent, support such conclusion, and that, by its use, all the inconveniences which attend the use of diluted vapour or the administration of the sponge may be obviated.

Yours, &c.,
A. H. Jacob, M.D. Dub., F.R.C.S.
79 Harcourt St., Dublin.

◆

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—It seems to me from my experience in watching operations at Moorfields Ophthalmic Hospital, which I have recently done, in order to make up my mind on the question of anæsthetics, that there is every probability that ether will ere long take the place of chloroform. There can be no doubt that statistics are in favour of ether, and, as far as I can see, it is administered with facility and safety.

I am, Sir, yours faithfully,
Charles R. Drysdale, M.D.
London, Feb. 17, 1873.

THE IRISH COLLEGE OF SURGEONS AND ITS REPRESENTATIVE IN THE MEDICAL COUNCIL.

The Council of the College at its last meeting did not arrive at any determination as to the course which should be pursued in regard to Mr. Hargrave's continued assumption of the office of Representative of the College.

The Council is, indeed, placed in a position by Mr. Hargrave's persistence in over holding, from which it is difficult to suggest means of escape or to blame it for want of energy and decision.

At the last meeting a resolution was proposed which would have declared peremptorily and officially the want of confidence of the Council in Mr. Hargrave's competency, but it was not adopted, having been thrown out by the negative vote of Mr. Hargrave himself.

Without doubt the Fellows of the College would readily and unanimously give expression to a similar opinion if it were thought right that they should be called together by requisition for the purpose, but we hesitate to advise an assembly of the College because Mr. Hargrave's attitude towards the Council in presence of an unanimous demand for his resignation affords no hope that he would yield the discreditable position which he occupies even to a decisive and unanimous vote of the Fellows.

If it appears to the Council, that no further means is open to them to secure a proper, effective, and creditable representation of the College at the coming meeting of the Medical Council, at least it will be proper for them to relieve themselves of the responsibility of Mr. Hargrave's proceedings. They cannot be considered to have done all that in them lies, to protect the College from misrepresentation, until they have, by a decisive and unmistakeable vote, put it out of any one's power to say, that when Mr. Hargrave has expressed himself the College has spoken, and has said all that might be said as to the critical question on which a Representative would be called upon to speak. If the Council cannot send forward a spokesman in whom they have confidence, at least they should repudiate liability for what may be spoken without authority in their behalf.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this request.

All communications intended for insertion must bear the name and address of the writer; not necessarily for publication, but as a voucher of good faith.

Subscriptions in the United States.—A correspondent has drawn our attention to the fact, that some of the houses in the United States are charging the enormous figure of 15 dollars per annum (more than £3) for supplying this Journal to different parts of the States. We beg, therefore, to state that we shall be happy to supply the same regularly, post free, per annum, if paid in advance, for considerably less than half this amount, viz., six and-a-half dollars (about £1 [illegible] 0d.), either direct from our offices in this country, or through our recognised agents in the United States.

Law respecting Periodicals, Newspapers, &c.—1. Subscribers who do not give express notice to the contrary, are considered as wishing to continue their subscriptions. 2. If Subscribers order the discontinuance of their periodicals or newspapers, the publisher or publishers may continue to send them until all arrears are paid up, and Subscribers are held responsible for all numbers sent. 3. If Subscribers neglect or refuse to take the periodicals or newspapers from the office to which they are directed, they are held responsible till they have settled their bills. Sending numbers back, or leaving them in the office, is not such notice of discontinuance as the law requires. 4. If Subscribers remove to other places without informing the publisher, and their periodicals or newspapers are sent to the former directions, they are held responsible.

Degrees in Absentia.—A correspondent has clipped a paragraph from a Shrewsbury paper, about which he asks whether the Fellowship of the Faculty of Physicians and Surgeons, Glasgow, is granted *in absentia?* Our correspondent will have noticed that the recipient in question was already a Licentiate; the Fellowship being an honorary distinction, and not a license to practise, he is entitled thereto without visiting Glasgow, if duly elected. Our correspondent is quite in error in supposing that it can be purchased for £21, or at any price.

Dr. L.—So soon as space permits.

Quack Prosecution Fund.—Subscriptions are much needed to carry on the prosecutions already initiated, they may be sent to the care of Mr. Berkeley Hill, 55 Wimpole Street, W., or to the Secretary to the Society for the Suppression of Vice, 28 Lincoln's-inn-Fields, London. We are happy to again give space in our columns on behalf of this excellent cause, which should be supported by the Profession of all large towns.

The Cancer Quack.—This individual, whom we exposed some few months ago, has again cropped up with letters from "grateful patients" (!) which are now being sent round to the editors of the general press. We hope none will be weak enough to give him the publicity he desires.

Abernethy and the Candidate.—A very good story is told of Abernethy in the last number of the *Students' Journal*. Dr. Abernethy, at the examination of the College of Surgeons, questioned one of the candidates as follows:—"Supposing that a man was blown up by gunpowder, what would be the first steps you would take?" *Candidate:* (*very cool*) "Wait till he came down again." *Doctor:* "Just so! and suppose I was to kick you for that impertinent reply, what muscles should I put in action?" *Candidate:* "The flexors and extensors of my right arm, for I should floor you instantly." *Doctor:* "Stand down."

Mr. W. H. D.—The portion excised is somewhat contradictory to the first part of your letter, it would, moreover, raise discussion upon points which have been frequently before our readers, and for which we cannot now afford space.

THE MIDLAND RETREAT

(Near Maryborough, on the Great Southern and Western Railway,)

FOR THE RECEPTION AND TREATMENT OF THE INSANE, and of persons suffering from a disturbed state of the Nervous System, under the direction of Dr. JACOB, Physician to the Maryborough District Lunatic Asylum (260 patients), Surgeon to the Queen's Co. Infirmary, &c.

THE ESTABLISHMENT consists of separate and commodious residences for the reception of Ladies and Gentlemen. Each situated on extensive grounds, with large, well-enclosed gardens. They are handsome, well-furnished country residences, where the patients enjoy the comforts and indulgences of a private house. Restraint is not, under any circumstances, practised, and the closest attention is paid to the medical treatment and general health of the patient.

APOTHECARY ESTABLISHMENT FOR SALE.

TO be SOLD by PRIVATE CONTRACT, the INTEREST of the REPRESENTATIVES of the late H. P. SMITH, Esq., L.A.H., in that Shop and Premises in the main street of the town of Strabane, in which the business of an apothecary has been successfully and extensively carried on for a great many years. The business has been conducted since the death of Mr. SMITH by his Representative, and is at present in a flourishing condition. The receipts and sales of the business for several years past have averaged a sum exceeding £600 each year.

This is the only apothecary establishment in Strabane, a town of 5,000 inhabitants, 13 miles distant from Derry, and surrounded by a populous and rich district of country.

The stock of medicines at present on hand is large, and the shop fixtures are excellent, being almost as good as new.

The premises are held by lease for 30 years from the 1st November, 1866.

Proposals by intending purchasers will be received by the undersigned up to the 1st of March next.

Strabane, 28th Jan., 1873. THOMAS LYLE, J.P.

THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.

PATRON:—H.R.H THE PRINCE OF WALES.

This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develope the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £35 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote.

Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c., can be had at the office,

40 MOLESWORTH STREET, DUBLIN,
W. O'NEILL, Secretary.

The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements, from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

The scale of charges is as follows:—

Seven lines and under	£0	4	0
Per line afterwards	0	0	6
One quarter page	1	5	0
Half-page	2	10	0
One do.	5	0	0

When advertisements are given for a series of insertions, a very considerable reduction from the above scale is made.

☞ Advertisements for Insertion in this Journal must be at the OFFICE, on SATURDAY, by TWO o'Clock.

Established 1848.

PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY LL.D., M.R.C.S., F.L.S., &c. (KING'S COLL.), and Author of VIA MEDICA,

Has always upon his books a large number of desirable Investments and available Appointments for negociation.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

COMPETENT ASSISTANTS provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

PRACTICES AND PARTNERSHIPS NOW OPEN for Negociation (in addition to those advertised in Dr. Langley's List (which is sent post free on application).

Y 629. In one of the best towns in the Midland Counties, the Leading PRACTICE for TRANSFER. The connection is old-established, and twelve months' introduction might be relied on to secure its transfer to a suitable gentleman. Average receipts, £1,600 a year. Midwifery fees, chiefly £5 5s. A few cases of old patients at lower rates. Visits, 3s. 6d. to 5s. without medicine. Patients of the best class. Terms, 1½ years' purchase, of which £1,200 would be required to be paid down.

Y 628. MIDLAND. In a prosperous manufacturing town, an old-established PRACTICE, producing £600 a-year, and capable of immense increase. Patients middle-class. Convenient house in a suitable situation. Rent, £70. Midwifery, £1 1s. and upwards. One horse does the work. To a young professional man the Practice affords a safe investment.

Y 627. SUBURBAN NUCLEUS. LONDON. A gentleman having a branch Practice in a pleasant Suburb, at a considerable distance from his own residence, desires to transfer it. £200 income might be safely relied upon in the first year. Two appointments yield £60. All expenses, small premium, £100, of which part may be left on security.

Y 639. LONDON SUBURBS. Good CLASS PRACTICE with Residence. The connection has been established nearly two years, and is wholly transferable to a suitable gentleman. The receipts from Practice are at the rate of about £430 a year; from residents in the house, £195 a year. The house is large, well situate, and can be taken furnished, with Surgery, &c., as it stands. The Midwifery fees are chiefly £2 2s. The Practice is in a good and improving neighbourhood with Railway Station, and Tramroads close to the residence. The Incumbent having been elected to a valuable public appointment is retiring in consequence.

Y 638. PARTNERSHIP in a PROVINCIAL PRACTICE, realizing £1,700 a year exclusive of appointments. The population of the town is 10,000, and there is very little opposition. The district is thriving and prosperous. One-third share for disposal, with succession to the whole in five years if desired. The junior must be well educated in his profession, and accustomed to good society.

Y 637. In a large Town in the West of England. A well-established PRACTICE, which, in consequence of ill-health, has recently realized only about £400 a year, but which is capable of almost unlimited extension. As the patients reside within a narrow area, no Assistant or horse need be employed. Midwifery fees from £1 1s. to £3 3s.; appointments, £100 a year. The residence is pleasantly situated; contains ten rooms. Rent, £33 a year. An effective introduction can be given, and a moderate premium would be accepted.

Irish Poor-Law Intelligence;

UNDER AUTHORITY OF THE

IRISH MEDICAL ASSOCIATION.

BELFAST BRANCH OF THE ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

THE stated annual meeting of the supporters of this local branch of the above excellent and invaluable Society was held last week in the Chambers, 33 High Street. The day being very inclement, the attendance was limited. Amongst those present were—Dr. T. H. Purdon, the permanent President, who occupied the chair; Dr. H. S. Ferguson, Dr. James Moore, Dr. M. M'Gee, Surgeon H. M. Johnston, and Dr. Stewart.

The proceedings of the last annual meeting having been read, were confirmed, and signed by the chairman.

According to the financial statement of the past year, it appeared that the total sum transmitted to the parent Society was £113 13s. 9d., of which amount the subscriptions were £63 13s. 9d., and the donations £50, the difference in the disposal of these respective collections being that the donations are placed out at interest, and the subscriptions allocated for the immediate purposes of the Society. Some discussion took place on the comparatively small aggregate amount of the above collection, when proportioned amongst the practitioners of the entire of the County of Antrim, including Belfast, and a large portion of the County of Down, the Newry branch being a separate one. It was pointedly observed with regard to several of the large towns in the County Down, that the friends of the Society were "few and far between;" and that especially as regarded Downpatrick not a single subscription was received from it; that in Ballymena, out of nine Members of the Profession there, but one was a subscriber. Lisburn, however, it was stated, showed a different spirit in the way of benevolence towards those needing the same—four out of six of its Medical men being regular and good subscribers, besides several of the respectable laity in that thriving town, which so greatly redounded to their credit, and which also spoke so well for the efficient services there of Surgeon Musgrave, so long a warm friend of the Society. Belfast itself, it was remarked by Dr. M'Gee and others, had nearly 100 resident practitioners, but of this number little more than a third held in remembrance the claims on them of their poorer and afflicted brethren, but which was attributed in no small measure to deficient house-to-house visitation, and, accordingly, the meeting to-day resolved on adopting a new system of collection, by taking the town in its Poor-law division of wards—Dock Ward being allocated to Dr. M'Gee and Surgeon H. M. Johnston; St. George's Ward to Dr. T. H. Purdon and Dr. H. S. Ferguson; Cromac Ward to Dr. James Moore and Surgeon Martin; Smithfield Ward to Dr. Harkin, J.P., and Dr. Brice Smyth —which new system of collection, it was hoped, would be productive of the best results, the several collectors not being limited to calling upon the professions alone, but upon others also who, being blessed with this world's goods in abundance, it was considered would only need to be asked to give a measure of that aid which would only be a fair return for the disinterestedness and liberality in which the Medical Profession gave the benefit of their services to the public at large.

The meeting having heard a report from Dr. Jas. Moore of his mission to some unassenting country districts during the past year, which was not very encouraging in its results, he was requested to continue using his influence in obtaining the aid of those who had hitherto been oblivious of their duty in that respect.

The President and Surgeon Johnston were appointed a deputation to attend the ensuing annual meeting of the parent Society in Dublin.

The following subscriptions and donations for the ensuing year were now handed in, viz.:—Dr. T. H. Purdon, £25, donation; ditto annual subscription, £5; Mrs. Harrison, per ditto, £5, donation; Miss Lepper, Guernsey, per ditto, £1; Surgeon H. M. Johnston, annual subscription, £2 2s.; Dr. H. S. Ferguson, £1 1s. ditto; Dr. M. M'Gee, £1 1s., ditto; Dr. W. A. M'Keown, £1 1s., ditto; Dr. James Moore, £1 1s., ditto; Dr. R. Stewart, £5, donation; ditto annual subscription, £1 1s.

The meeting having pointedly referred to the munificent donation of £100 lately given to the Society by Surgeon Johnston, a vote of thanks was passed to him by acclamation for this practical evidence—one so worthy of imitation—which he had given of the warm interest he felt on behalf of the all-important objects of this Society.

MORTALITY OF DUBLIN AND THE SUBURBAN DISTRICTS.

THE deaths registered in the Dublin district during the last week represent an annual mortality of 43 in every 1,000. In London the death rate was 24, in Glasgow 35, and in Edinburgh 26.

In the Dublin district the births amounted to 158, the average being 186.

In respect to the very high death rate for the present week, it is necessary to state that this does not represent the true death rate, but refers to the registered deaths. Of these 78 took place in the South Dublin Union Workhouse—49 during the month of January,—and 29 during the present month. Such irregularity in furnishing the returns to the Registrar from large public institutions detracts very much from the value of the "Weekly Returns."

Six deaths were caused by scarlet fever, 7 by whooping-cough, 4 by diarrhœa, 2 each by measles and typhoid and 4 by croup.

The deaths of 11 children were referred to convulsions.

Fifty-four persons died from bronchitis.

Apoplexy was the cause of 4 deaths, and paralysis of 8.

Heart disease proved fatal in 13 instances.

Two deaths were ascribed to kidney disease, and 1 to Bright's disease.

Phthisis killed 28 persons, mesenteric disease 2, hydrocephalus 6, and scrofula 1.

Seven deaths were referred to cancer.

Two deaths were caused by fractures and contusions, and 1 death was suicidal.

The ages of three persons were stated to have been 90 years and upwards.

SLIGO DISPENSARY.

A SPECIAL meeting was held at the dispensary for the election of an apothecary. It will be remembered that the committee had advertised for an apothecary several times, and as no candidate presented himself, they were obliged to raise the salary. They then elected Dr. Johnston, who was objected to by the commissioners as being over age.

The Secretary read the minutes of the last day's proceedings, and the advertisement published in the MEDICAL PRESS and in the local papers.

He then read the applications, from Dr. King Nixon, of Ballyfarnon, from Dr. P. O. Devanny, of Dublin (formerly of Dr. Johnston's establishment in Sligo), and from Dr. Johnston.

Rev. Mr. Griffith—I propose Dr. Johnston.

Mr. Lyons proposed the appointment of Dr. Nixon. He was a young man coming with excellent testimonials, and was apparently an active man, having a good deal of work in him. This young man had already filled a similar position in Ballyfarnon, therefore he had some experience in the work, and his removal from Ballyfarnon was apparently regretted by the people of that place.

Mr. Rowlett seconded the appointment of Dr. Nixon. In applying for the present post for Dr. Nixon, Mr. Rowlett said he did so because he wished to open an apothecary's shop in Sligo. That was as much his object as to live by the situation of apothecary to the dispensary.

Mr. Tighe proposed the appointment of Dr. Devanny, and he said his reason for doing so was that he took the youthfulness of this candidate into consideration, as well as the high character and good testimonials he brought with him. It would be a wise thing to elect a young man like Mr. Devanny, as that put the prospect of paying any superannuation into the far distance.

There voted for Dr. Johnston—7.
For Dr. Devanny—5.
For Dr. Nixon—4.

The chairman then took away the name of Dr. Nixon, and took the votes as between the other two in the usual way. Dr. Johnston received 10 votes, and Dr. Devanny 6.

The chairman declared Dr. Johnston duly elected, and the meeting broke up.

◆

THE MEDICAL OFFICERS OF CAVAN UNION.

The guardians having declined to raise the salaries of their Medical officers, in compliance with a memorial from them, the Local Government Board have addressed the guardians on the subject, informing them that the salaries of the Medical officers in the Cavan Union are "considerably below the average salary of the dispensary Medical officers in Ireland; and they recommend the guardians to reconsider their resolution on the subject." The matter is to be reconsidered by the new board of guardians on its first meeting on the 1st of April next.

FANNING'S INSTITUTE, WATERFORD.

A letter was read forwarding extract from the will of the late Dr. Connolly, of Tramore. The extract was to the effect that the testator bequeathed £1,100 to the Fanning Institute, under the following conditions:—The amount to be invested in Government securities, and the interest to be applied to the support in the houses of six respectable poor people, to be selected, if possible, from those afflicted with total or partial blindness, and that the fund shall be called "The Anna Maria Fund," in commemoration of his beloved daughter.

DEATH OF DR. T. B. MACAULIFFE, OF ABBEYFEALE.

We are pained to hear of the death of this popular Medical gentleman, after a brief illness, of typhus fever, which is said to be epidemic in the district at present. As dispensary and visiting physician of a large tract of country, his duties during and after the wet weather at Christmas period brought on a sharp attack, culminating in the malady which was the immediate cause of his lamented death. For some time Dr. MacAuliffe bore up against the disease, and hopes were entertained that the crisis was over. His constitution had, however, been undermined by overwork; he was not able to battle with the malignant disorder, and he succumbed at his post, in the height of his professional and private usefulness, on the afternoon of the 5th inst. Few death in this county could cause such sorrow as this will excite under the circumstances. He was able and successful as a doctor, amiable and upright as a friend, of irreproachable moral character, and beloved by the people. The old Greek proverb, "They whom the Gods love die young," is in this case painfully illustrated. Those who knew Dr. Macauliffe said, during his illness, that he was to good to live, and it is melancholy when virtue and worth meet such a fate, but in duty in this, as in all things, we must bow before the will of God, and await from him the "exceeding great reward," sometimes denied with length of life and enjoyment in this world.

◆

The Board of Management of the Belfast General Hospital report E. Benn, Esq., of Glenravel House, Ballymena, has generously presented to the Hospital a sum of £1,000 to be applied to the funds for the building of the Convalescent Hospital.

The Board further report several other munificent donations promised to these funds, as they are anxious to proceed with the building as speedily as possible by reason of the engagement they entered into with the late generous donor of the ground that the building should be erected in two years from March, 1872.

They have accordingly made arrangements with a view to proceed with the building early in the ensuing Spring.

The Board also acknowledge a donation and bequest to the funds of the Hospital by the late Dr. McWilliams of £100.

MEDICAL FEES.

The following tariff has been adopted by the Ulster Medical Society and is intended to indicate the minimum of remuneration to which any Practitioner is entitled, whatever be his professional rank, or the extent of his practice. It is expected to be especially valuable for the guidance of junior Practitioners, and as a reference in disputed charges. Those members of the Profession whose extensive practices make their time specially valuable, are individually best able to estimate the higher amount of remuneration to which their Professional qualifications entitle them. We publish this tariff for the information of our subscribers, but desire that it will not be inferred that we think it possible or desirable to fix any minimum scale, or that we consider the fees named in it as adequate remuneration for any practitioner, or for any part of Ireland. We rather doubt the advantages of fixing such a "commercial treaty."

In the following table patients are divided into three classes, the basis of division being the rent of their residences:—

	RENTAL.
Class I.	£10—£25.
II.	£25—£50.
III.	£50—£100.

TABLE OF FEES.

	Class I. s. d. s. d.	Class II. s. d. s.	Class III. s. s. d.

Vaccination by regular attendant, ...	By number of visits.		
Vaccination by other than the regular attendant, ...	One and a-half the visits.		
Mileage outside the Borough Boundary, ...	1/6	2/	2/6 per mile

PAYMENT OF CORONER'S WITNESSES.

C. D., a legally qualified Medical practitioner in Dublin, was called hastily to see a man who had fallen from a height and was killed. Next day he was called on by the police and requested to attend the inquest which he did, though he did not receive a regular summons. He was there examined and gave his evidence. A few days afterwards he received an order from the Coroner on Town Clerk of the Dublin City Corporation for £1 1s. On application for that sum he was, after several ineffectual requests for its payment, informed that "the Committee did not consider his evidence necessary at the inquest and would not pay." At his request we obtained the following advice :—

C. D. having been noticed by the police, and examined by the Coroner, is certainly entitled to his fee—it has been decided over and over again by the judges—that the Coroner has the sole discretion of holding an inquest, and of examining a Medical witness, and where grand juries have refused to present a fee for the Medical man the court has ordered them to do so, so that unless there is some special clause in the Corporation Act, empowerring them to refuse payment, there can be no question, once the Coroner gives his order for payment, C. D. can compel them to pay.

Acting on our advice C. D. informed the Committee that if his fee were not paid he would proceed to recover it at law. The Committee discovered their error and paid at once.

DEATH OF DR. GORE, OF WATERFORD.

THIS gentleman died on the 10th inst., at his residence, Newtown, after a protracted illness. For a number of years past he held the position of Coroner for this district, and since the resignation of Dr. Carroll, he was Surgeon-Major of the Waterford Artillery Militia.

WE regret to have to report the very dangerous illness of Dr. Wm. Irwin, Medical officer of the Belleek dispensary, caused by a dissecting wound.

CHEMISTRY OF THE URINE.

WITH the new year, the *Boston Medical and Surgical Reporter* begins in a new form and is printed on toned paper. The first number contains the beginning of a capital report on Medical chemistry. We extract a couple of paragraphs as specimens of the skill with which it is compiled by Dr. E. S. Wood.

Modified Pettenkofer's Test for detecting the presence of Biliary Acids in the Urine. (G. Strasburg, *Archiv. d. Physiol.*, Bd. iv., p. 461.) This test is applied in the following way: The urine to be tested is mixed with a dilute solution of cane sugar, and a piece of filter paper is moistened with the mixture and dried. After drying, a drop of pure concentrated sulphuric acid is allowed to flow over the paper, when a beautiful purple color will be produced if the slightest trace of biliary acids be present.

This is much more delicate than the ordinary method of performing Pettenkofer's test, in which the sulphuric acid is added directly to the mixture of urine and sugar. The author states that he has detected by this method the presence of biliary acids in a solution containing only 0.00003 gramme (0.00046 grain), and the writer has repeatedly detected them in a liquid by the modified test, when the ordinary test gave a negative result.

On the efficacy of the Methods used up to the present time for detecting small quantities of Sugar in the Urine.—J. Seegen *Fres. Zeit.*, x., p. 501) from many experiments draws the following conclusions in regard to the sugar tests:—1. That we have no re-agent which will with absolute certainty, and with the exclusion of other substances which act in an analogous manner and which may at the same time exist in the urine, detect very small amounts of sugar in the urine. 2. That therefore all statements as to the presence of very small quantities of sugar in the urine in many physiological and pathological circumstances, are somewhat doubtful. 3. That normal urine does not contain such an amount that its presence can be detected with certainty. 4. That normal urine contains a small quantity of reducing substances, but that a portion of these is sugar, is not surely determined.

Very careful experiments by Maly (*Fres. Zeit.*, x., p. 382) have been performed to test the delicacy of the best and most common of these tests, viz., Trommer's test, by adding to normal urine different amounts of pure grape sugar. He found that urine to which 1-10th per cent. of sugar was added underwent no change upon the addition of potassic hydrate sulphate of copper and heating the mixture, except a change to the normal yellow colour, and a precipitation of the earthy phosphates after the addition of the first re-agent. Urine to which 6-10ths per cent. of sugar was added, upon being subjected to the same treatment, changed to a brownish yellow colour, but no precipitation of the cuprous oxide took place. Upon the addition of 8-10ths to 1 per cent. of sugar, however, the precipitation of the yellow cuprous oxide (suboxide of copper) was produced. The delicacy of the test is shown by the fact that pure water containing 2-100ths per cent. of sugar, gave, when treated in the above manner, a precipitate of cuprous oxide. Hence there must be substances in normal urine which hold in solution the cuprous oxide formed. This action is due mainly to the presence of kreatinine, 28 milligrammes of which were found to be sufficient to retain in solution the cuprous oxide formed by the action of 10 milligrammes of sugar on sulphate of copper; it is also due partly to the presence of the colouring matters, since a smaller quantity of sugar could be detected after decolorizing the urine with animal charcoal than before.

If to the hot fluid which contains cuprous oxide in solution after the performance of Trommer's test, a little zinc oxide be added from the point of a knife, and the fluid be warmed again for a moment, a yellow layer consisting of a mixture of zinc and cuprous oxides will be deposited upon the white zinc oxide in the bottom of the test tube, the zinc oxide having displaced a portion of the cuprous oxide from the solution.

In conclusion, the advice is given, that in those cases in which there is a doubt as to the presence of sugar after the performance of Trommer's test, the urine should first be decolorized with animal charcoal, then made alkaline by the addition of an equal volume of sodic or potassic hydrate, and finally sulphate of copper added until a small quantity of the greenish blue hydrate of copper remains undissolved upon shaking. If after heating, no cuprous acid is precipitated, add zinc oxide as mentioned above, and then if no yellow layer is deposited after subsidence of the solids, the conclusion may safely be drawn, that no appreciable amount of sugar was present in the specimen under examination.

MR. LIDELL, of New York, strongly recommends a solution of one part carbolic acid, in from 500 to 600 parts of water, to be used for inhalation by means of a spray machine in chronic bronchitis.

Nomobromate of Camphor in Delirium Tremens

DR. A. MCLLEAN HAMILTON, gives in the *New York Medical Journal*, a case in which the foregoing remedy had been used to overcome obstinate wakefulness, in doses of five gr., with the most perfect success.

IN the *Nashville Journal of Medicine and Surgery*, a very interesting case of hepatic abscess is recorded by Dr. James F. Wads, Surgeon United States Army, from which in six months there had been removed by means of the respirator 418 oz. of pus, or three and a half gallons. The largest amount removed at one operation being 144 oz.

ACCIDENTS IN FLAP EXTRACTION OF CATARACT, AND THE METHODS OF AVOIDING THEM (a).

By Archibald Hamilton Jacob, M.D.Dub., F.R.C.S.,

Chief Surgeon to the Dublin Eye and Ear Infirmary, Ex-Ophthalmic Surgeon to the City of Dublin Hospital.

(Continued from p. 145.)

Fixation.

The ordinary fixation forceps I have found very ineffective. Its bite is very minute and very sharp, and it is liable to tear away from its hold on the conjunctiva just at the moment when its services are most wanted, I have, therefore, obtained from Paris a forceps—of which the points of seizure are depicted in Fig. 2—which takes a wider and more effective grip, and inflicts upon the conjunctiva, no injury of more moment than a contusion. Mr. Soelberg Wells, Mr. France, of Guy's hospital, and others, direct the eye to be seized a little below or above the cornea, according as the section is to be made above or below. Mr. Macnamara, on the other hand, advises the hold to be taken close to the equator of the eye, and internal to the cornea, I think the latter method of fixation is much the best, for I have found that if the hold be taken below or above, the position of the operator's hands is awkward, and the eye rotates more or less on its axis when the pressure of the puncturing knife is applied to it. My own rule is to seize the conjunctiva immediately above the spot where I mean to make the counter-puncture, and thus I not only keep my left hand out of the way, but I have my fixed point directly opposite to the point of entry of my knife, and the exact place for my counter-puncture is marked for me.

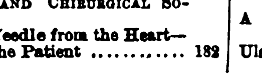

Fig. 2.

The Flap Incision.

All that I have said as to the use of the left hand, the placing of the patient under the influence of ether, and the fixation of the eyeball has had special reference to the making of a perfect flap incision. This is not only by far the most difficult manœuvre of the operation, but on the successful performance of it, the subsequent steps of the operation and the success of the result mainly depend. It is unnecessary for me to recapitulate the effect of making the flap too large or too small, or of wounding the iris.

The appended illustration (Fig. 3) depicts the two most usual malformations of the flap—one in which the puncture is made too much within the scleral junction of the cornea, and the other where the flap was not made large enough. In either case the examination of the lens would be difficult, and attended with danger of escape of vitreous.

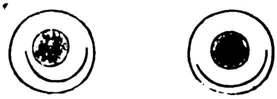

Fig. 3.

The movement of the knife in making this incision must be steady, even, and continuous, the plane in which it moves must not be altered, and the incision ought, if possible, be completed in a single stroke of the knife. To ensure its being so, there are several little details which are worthy of mention. In the first place, the point of the knife must be of extreme acuteness, so that it may pass through the cornea almost without pressure. Insignificant as this precaution may be, it is of much importance. If much force be required to make the puncture, the knife enters the anterior chamber with a sudden jerk, and being driven across *per saltum*, is again suddenly checked by impinging in the cornea at the opposite side, probably with loss of aqueous humour, and consequent embarrassment with the iris. A properly sharpened knife makes its entry almost imperceptibly, and being quietly and steadily advanced, blocks the incision which it makes, and gives time for the selection of a proper point for the counterpuncture.

(a) Read before the Surgical Society of Ireland.

I think it is very desirable that the whole section should, if possible, be made by one sweep of the knife, and that the sawing process which some authors recognise as a part of the operation should be avoided.

As long as the knife is pushed forwards it will, if rightly held, close the incision completely, and there will be no possibility of escape of the aqueous humour; but the moment it is slightly withdrawn, for the purpose of sawing through the remaining bridge of cornea, the aqueous chamber collapses, and the iris may probably fall forward on the blade. Therefore, if possible, the flap should be made by one single forward movement, and, if possible, it ought to be unnecessary to withdraw it until the full section be completed. The operator may be prevented from effecting this object, either by the point of the knife impinging against the patient's nose, or by the eye turning a little inwards, yielding before the pressure of the knife.

To prevent this, the eyeball must be held very firmly, looking straight forwards in the axis of the orbit, or even slightly everted, and a suitable knife must be used. The Beers knife, which I like best, and which is illustrated in Fig 4, is very short in the blade, and sufficiently wide at the base of the triangle to complete the flap, and it tapers from a very acute point to a rather thick heel. The angle of the edge with the back must not exceed a certain degree of obtuseness, or it will not cut through the cornea readily and easily. Many extraction knives are made so long and narrow that, although they enter the cornea and make the counterpuncture with facility, they cannot be passed sufficiently far to make the necessary section without drawing them and sawing out.

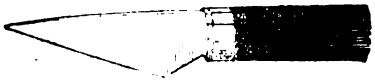

FIG. 4.

The flap should be made to occupy only a little less than half the cornea, for I think that the increased risk of its sloughing afterwards—if there be any such danger—is more than compensated for by the facility with which the lens escapes in its entirety without the use of scoops, and without the necessity for much pressure on the eyeball. The low vitality of the cornea has been much talked of lately, in connexion with Graefe's method of linear extraction, in which the incision is made, if possible, in the corneal margin of the sclerotic. If the incision in flap extraction be carefully made, the greater part of it will be in the same situation; but I very much doubt that a corneal incision is less likely to heal than one in the sclerotic, or that a large incision is less likely to heal than a small one. In two out of eight cases of scoop extraction, in which the incision was less than a third of the cornea, I have had sloughing, and I believe that when misfortune occurs in flap extraction, it is the result of impaired nutrition in the patient himself, and not specially in his cornea, and that a small flap would be almost as likely to slough as a large one. By making a sufficient flap in the first instance the operator is saved the use of a secondary knife, has no necessity to exercise a degree of pressure to extrude the lens which may extrude the vitreous also, and does not incur the danger of leaving scraps of cortical cataract behind—a matter to which, as I have said before, I attach much importance.

With a very large flap there is, however, some danger that the lens and a part of the vitreous may escape precipitately if the section is roughly completed, and if this be done at the time of making the flap, it is necessary the last bridge of conjunctiva shall be divided very fully and quietly, and the fixation forceps let go same instant or a second previously. A much safe better practice—one which is a comparatively suggestion—is that the operator shall not divide th bridge of the conjunctiva at the time of making th incision, but shall withdraw the knife and proce lacerate the capsule, and when that is effectively shall divide the remaining connexion of the flap Maunoir's probe-pointed scissors. This is an ex suggestion, and I have found it to add much to the and steadiness of the operation. In the first pl allows time to remove the fixation forceps; it enabl laceration of the capsule to be effected with less da injuring the iris, which cannot prolapse as it often when the section is suddenly completed; and, lastly, last connexion of the flap is severed by the scissors out any traction on the cornea, and escape of the le vitreous are less likely to take place. Furthermor operator is afforded time and opportunity to judge wh his flap is large enough, and to extend it if necessary can make sure that the capsule is thoroughly torn before he proceeds to evacuate the lens.

(To be continued.)

◆

MALIGNANT DISEASE OF THE OVARY UTERUS.

AT the usual weekly meeting of the Dublin Path Society on Saturday last, Dr. P. J. Hayes, Surgeon Mater Misericordiæ Hospital, laid before the Society man of malignant disease which attacked, he believed, first instance the left ovary of a patient, extended, the right and posterior aspect of the uterus, and which as he had been able to judge from a section already seemed to have obliterated the uterine cavity. The of the case was, that a woman named Forrester was ad to the Mater Misericordiæ Hospital on the 27th of J suffering from abdominal tumour, her size equalling th woman who was in the sixth or seventh month of preg She complained greatly of abdominal pain, and state she suffered a good deal from constipation, but otherw appeared in fairly good health. The statement was, th had been healthy up to three months prior to her ad to hospital, and about that time she suffered from consi pain in the lower portion of the abdomen or hypo region. Soon afterwards she noticed swelling; this s increased, and at last her sufferings became almost intole and seemed to be due to flatulent distention of the st and intestines. On examination, he detected a firm tu which might be readily moved from side to side, and wa noticed on the lower part of the abdomen. The upper p of the abdomen was clear on percussion, but some duln the lumbar regions existed. The opinion then formed that the woman was suffering from an ovarian tumour determined to watch the progress of the case, and incl the belief that it might be a case suitable for the oper ovariotomy. The sufferings of the woman increased no standing the treatment which was employed, and so opinion changed, and he came to the conclusion th suffered from malignant disease. That opinion was the partly of the rapid growth of the tumour and the appe of the woman, which altered very much for the worse short period of time, and that opinion was confirmed in s measure when the operation of tapping was performed. W the view of relieving the distress the patient suffered from, determined to try if the tumour could be reduced in bulk paracentesis; but owing to the tense, indistinctly-fluctuat feel of the tumour, he concluded that tapping with the tro would not be productive of much result, and he reques Dr. Hayden to allow him the use of an improved form aspirator. He (Dr. Hayes) on the 15th February punctu the cyst with the largest tubular needle, and though aspirator was very thoroughly exhausted of air, yet not m than about an ounce of thick tenacious fluid escaped.

consequently withdrew the needle, not having succeeded in reducing the size of the tumour. He decided that it was of a malignant character, and on the 20th the patient died. The *post-mortem* examination revealed that the tumour was attached to the parietal peritoneum laterally, but the anterior surface was free, save below where the uterus was incorporated in the wall of the cyst. The peritoneal sac contained about two gallons of fluid, but the tumour itself was the chief point of interest in the case. They would observe that within the tumour was a substance partly colloid in appearance, and also resembling medullary sarcoma. There were secondary cysts in connection with the wall of the principal mass. Posteriorly and on the left side a mass of medullary matter connected the tumour with part of the small intestine. The mesentery was to a considerable extent, infiltrated with this medullary substance, and melanoid spots existed on portions of the intestinal wall. The lower portion of the large intestine, especially the sigmoid flexus, was intimately adherent to the tumour, so that it was rather difficult during the *post-mortem* examination to pass a long tube through it. This condition explained the fact that constipation was so obstinate, and flatulent distension of the intestines so distressing. An examination of the vagina was made during life, but the os uteri could not be felt; the upper portion of the vagina was dilated towards the left side, forming a *cul de sac*, into which the finger passed beyond the os.

The uterus was adherent to the anterior part of the cyst, and though a longitudinal incision failed to show any uterine cavity, yet a transverse division of the uterus made before the Society revealed a small cavity in the posterior part, which was intimately related to the wall of the cyst. The uterine appendages of the left side seemed to be incorporated with the tumour. The right ovary also seemed to have been engaged in the great diseased mass. The patient died, exhibiting symptoms of exhaustion and slightly delirious. She expressed herself as being relieved after the operation, but that must have been more or less imaginary on her part, as there was no reduction in the bulk of the tumour. She was about forty years of age, and married. About two years after marriage she gave birth to a son, and eight years subsequently had a miscarriage. She menstruated regularly, even during the period of her illness.

◆

PECULIAR *POST-MORTEM* APPEARANCES OF THE HEART AND BRAIN IN A CASE OF PARALYSIS AGITANS FOLLOWING NERVOUS SHOCK.

Dr. Nixon, at the last meeting of the Dublin Pathological Society, exhibited specimens taken from the body of a woman, aged about forty-five, admitted into the Mater Misericordiæ Hospital on the 25th ult., under the care of Dr. Cruise, suffering from a slight ulceration of the leg. Nothing unusual presented itself in the case, and it progressed favourably under treatment. About the 9th inst. one of the fever wardmaids suddenly told her that her daughter had been admitted into hospital suffering from severe typhus fever. She immediately commenced to tremble, and the tremor continued until the time of her death. It did not cease during sleep; it was occasionally accompanied by marked subsultus. About the eighth day following the first appearance of the tremor, she appeared particularly stupid; when given a drink, she carried the vessel to her lips, and then, as if forgetting the intent, put it down again. Her speech was hesitating. On the day following she could not protrude her tongue; she was unable to speak; the sphincters were relaxed unconsciously; there was profound muscular debility. About twelve o'clock on the next day she became suddenly convulsed. The convulsions continued with slight and decreasing intervals of cessation until the time of her death, which took place about two hours afterwards.

At Dr. Cruise's request he made the *post-mortem* examination, and, with his kind permission, he was enabled to lay the morbid specimens before the Society. On examining the heart, the left ventricle felt remarkably solid; it was distorted in appearance, the apex being considerably retroverted; its cavity was found much diminished in size; it would seem as if the ventricle had been surprised by death in the energy of its contraction; the curtains of the mitral valves were thickened and somewhat corrugated; the mitral orifice was slightly contracted, not admitting with ease the tips of two fingers. The aorta presented traces of atheromatous deposition and, on tracing the coronary arteries, patches of atheroma were discovered in their coats. The muscular wall of the left ventricle presented evidences of both fatty degeneration and interstitian fatty deposition. He remarked that these degenerative changes were most apparent in the muscular fibres contiguous to the parts of the coronary artery, which had undergone most change in structure. For instance, the wall of the right auricle lying in close proximity to the most diseased portion of the right coronary artery presented no traces whatever of transverse striation, and numbers of free oil globules could be seen scattered over the field of the microscope. On removing the spinal cord the meningo-Rachidian plexus of veins was found distended with black fluid blood. When taking off the calvarium, the dura mater was found more than usually adherent; it required his utmost force to separate it from the bony arch. When he slit up the dura mater, the surface of the brain presented an œdematous appearance. The sub-arachnoidean spaces were distended by serous effusion. The dura mater was intimately adherent to the cerebrum corresponding to the longitudinal fissure, and where it was joined by the falx-cerebri distinct plates of calcareous material were visible. The same changes in structure were found in the attached margins of the tentorium. The veins of the cerebrum and the sinuses were congested. No marked alteration in appearance was found in the interior of the brain or in its ganglia. He presented for examination the greater portion of the circle of Willis. They could see that the trunk of both internal carotids showed the same marks of calcareous deposition found in the dura mater, and at the point where the right internal carotid gives off the anterior and middle cerebrals a small saccular dilatation, evidently aneurismal, could be observed. The spinal cord presented nothing unusual in appearance, so far as external observation went; both lungs were found congested, the liver was enlarged, fatty and partially cirrhosed. The spleen was enlarged and soft; in its interior he found a large cyst, filled with serous fluid; there was also a small cyst found in the right kidney. He believed that in most of those cases of cystic disease of the spleen which were recorded a similar condition of the kidney or liver was present. There was some apparent atrophy of the cortical substance of the kidneys, but he could not say that they were otherwise diseased.

The points of interest connected with the case, he thought, were,—firstly, the existence of such an amount of disease affecting such vital organs without the development of any constitutional symptoms, and secondly, the relation which the symptoms preceding death had to the nervous shock. He would hazard the opinion that the case was one of senile paralysis agitans, which had been shown to arise sometimes from sudden nervous influences. This sudden shock must moreover have affected the already embarrassed circulation through the brain, disturbing its equilibrium, producing arterial anæmia, with concurrent venous congestion, which resulted in convulsions and death.

◆

NOVEL METHOD OF AMPUTATION OF THE FOOT FOR GANGRENE.

At the meeting of the Dublin Pathological Society on the 15th inst., Dr. R. W. Smith, Professor of Surgery in the University of Dublin, exhibited the leg and foot of a man who had been admitted into the Richmond Hospital about ten years ago. He had been working in the country, and a large block of stone had fallen on the anterior part of his foot, injuring the soft parts so severely that gangrene rapidly ensued.

The man came to hospital a week after the occurrence, and when gangrene had ceased to spread, and a line of separation had formed, the dead portion was removed by cutting in front of the cuboid and navicular bones, and making a long flap from the sole of the foot. Great difficulty was experienced in healing the stump, and a very long period of time elapsed before the man was able to return home, the cicatrix and the ulcer ulcerating and healing frequently.

Four years ago he was again admitted into the hospital, suffering from very extensive ulceration on the dorsum of the foot. At length, after several months he went to the country, and soon afterwards the core healed, and there was no subsequent attack of ulceration.

Last year he again appeared at the hospital, suffering from idiopathic, or Pott's gangrene of the other foot, which terminated fatally after several months' intense and unceasing agony.

The *post-mortem* examination showed that the ankle joint was perfectly sound. There was no anchylosis between the os calcis and astragalus. The cuboid and navicular bones had been joined to each other, and deeply excavated at their posterior aspects. With regard to the line of amputation he had followed, any one who looked at the specimen would see that it was neither Hey's operation, nor Chopart's.

The incision was carried through the median-tarsal range, detaching the fourth and fifth metatarsal bones from the cuboid and the cuneiform bones from the navicular, leaving behind four bones of the tarsus, viz., the os calcis, the astragalus, the cuboid, and navicular. A much longer stump was thus left than after Chopart's operation.

◆

Hospital Reports.

MERCER'S HOSPITAL, DUBLIN.

Some interesting cases of recent operation are at present under treatment in Mr. O'Grady's service. On February 10th, the right testicle of a delicate looking lad of 18 was removed for extensive tubercular disease, consequent on a kick received some eight months previously; a diseased state of the cord rendered it necessary to open up the tissues to the canal. A stout needle was passed through the cord previous to its division, the three vessels were tied separately with carbolised cat-gut ligature, the cords being cut off short. During the afternoon, in consequence of troublesome bleeding, it was necessary to reopen the wound and tie other vessels on the septum. The needle was removed after forty-eight hours, and in a week the patient was able to be up, and the wound is at present rapidly closing in, the patient walking out each day. In the adjoining bed is a man, aged over 50, from whom an extensive cancer of the lower lip of two years' duration, was removed on February 13th. The man had a large mouth with thick full lips, and as the disease extended almost from commissure to commissure a considerable bulk of morbid structure required removal. An H shaped incision was selected as allowing complete ablation of the disease without sacrifice of healthy tissue. The portion below the transverse bar of the H was carefully dissected from the chin and came nicely up for a new lip, being retained *in situ* by two hare-lip needles on either side and a few carbolised cat-gut sutures, the parts being also well supported by adhesive plaster and bandage to prevent too free motion of the lower jaw. The patient, a very feeble man, required stimulants freely for some days. The needles were removed on the fifth day, and the incisions found to be perfectly united, except the free border of the new lip which is slowly cicatrising. There was one enlarged gland beneath the left jaw which has become much reduced since the operation.

In the same ward is a case of very considerable interest, a healthy looking lad, eight years old, whose knee was severely wrenched two years ago. Till lately he has been treated by a bone-setter and farrier by various manipulatory processes and free severing with a knife of the integument on the inner side of the knee. The leg was much flexed, the joint being enlarged also very painful and tender, and obviously full of fluid which was pointing alongside the patella. A free incision made on Feb. 14th (the little boy being under chloroform) gave vent to about eight ounces of purulent matter with tubercular masses floating in it. That portion of the synovial membrane which comes into view was of a dirty slate colour und very unhealthy appearance. The limb having been straightened was placed on a carefully padded splint and warm water dressing applied. Since then the daily dressings have been scarcely tinged with pus and the circumference of the knee has reduced. The little fellow has been undoubtedly much relieved, but from the extent of local disease present, the issue of the case is questionable.

On February 19th, Mr. O'Grady operated for the radical cure of inguinal hernia and amputated the knee. The first case was a sickly looking lad of 13, who had a very large scrotal hernia on the right side. An incision having been made and the integument detached from the subjacent fascia, after the manner of Mr. Wood, the scrotal fascia was invaginated on the right forefinger and a curved needle with the eye near the point passed along the radial border of the finger and made to pierce the fascia and pass through the upper border of a very large external ring and then to perforate the integument. One end of a strong carbolised cat-gut ligature was now threaded into the needle's eye and the instrument withdrawn and unthreaded. The needle was now passed along the ulnar border of the finger and made to perforate the inferior border of the ring and come out through the original puncture in the integument, and having been threaded with the other end of the ligature was withdrawn. By traction on the ends of the ligature the loop disappeared through the perforation in the skin and became subcutaneous; the ends having been tied with a reef knot, held the invaginated fascia securely up. In consequence of the large size of the ring the same procedure was repeated at its lower part; a soft pad was placed in the groin and supported by the ordinary spica bandage. The progress of the case has been most satisfactory.

The second case was a man, over 50 years of age, who had cancer of the right leg for two years. The patient appeared to have been an intemperate man, he had large liver, bronchitis, and feeble circulation. The cancerous mass was firmly attached to the tibia and extended high up on the leg. Modified lateral skin flaps were made, their bifurcation corresponding to a little below the intercondyloid notch, behind and in front, to a couple of inches below the attachment at the ligamentum patellæ. The flap thus made covered the end of the femur admirably, the line of unison of the flaps being well behind in the space between the condyles. Several vessels required ligature and were all tied by carbolised cat-gut, the ends being cut off, the stump heads at the gastrocnemii were dissected out. Troublesome bleeding from the popliteal vein was arrested by the local pressure of a dossil of lint. Since the operation the patient has slept well and taken stimulants and food very freely. Altogether he seems to have held his own. Save for a small spot which has a dark and suspicious appearance, not so large as a shilling, on the free border of the outer segment, there has been no indication of loss of vitality in any part of the flap.

◆

NECKER HOSPITAL.

The following cases are reported at this hospital, which are of interest to the practical surgeon, with regard to the treatment of joints and synovial cavities :—

Case 1.—A woman, æt. 53, of good constitution, fell from a first-story window, and received a compound fracture of the patella with a penetrating wound of the joint. This wound was nearly the length of the patella, and gave exit to abundance of blood and synovial fluid.

The edges of the wound were drawn together and coated over carefully with collodion, the limb being adjusted in a splint. Cold irrigation was kept up continuously.

During the succeeding days there was not the least pain or inflammation; the joint became swollen without pain or redness. On the 22nd of June the wound was thought to be tolerably healed. On June 23rd some pain occurred, and finally, during the succeeding days, the wound opened and gave exit to synovial fluid, and considerable tume faction ensued. By rest and irrigation, the swelling gradually subsided, and on

Sept. 8th the patient was enabled to walk without a stick or support, though the motions of the joint were somewhat painful.

Case 2.—A patient, æt. 35, fell from a house and received a fracture of the olecranon, with a penetrating transverse wound of the joint.

The wound was immediately closed, and cold irrigation constantly applied. The limb was placed in a semi-flexed position. By a steady continuance in this treatment the wound healed and a useful joint was obtained. There were absolutely no bad symptoms.

Case 3.—A man, æt. 44, opened the wrist joint on the dorsal aspect by a fall on a sharp blade. The wound was a very severe one, and the lips were drawn together by three stitches of iron wire. For the next five days there was considerable tumefaction, and the wire sutures were removed; a few drops of pus escaped, the wound gradually healed kindly, and the joint recovered.

The results of these cases point to the great advantage of cold irrigation and rest, as succeeding the closure of the wound, and of avoiding the *nimia diligentia* of examining the condition of the parts too frequently.

Hydatid Cyst of the Spleen.

L'Union Médicale reports a case of an immense hydatid cyst of the spleen, under the care of M. Martineau. The tumour was punctured through the abdomen, and finally the opening was dilated with sea-tangle. Hooks of the ecchinococcus were detected in abundance in the fluid, and a large quantity of decayed hydatids were finally given exit to.

Treatment of Articular Rheumatism.

M. Dugardin Beaumetz has drawn attention to the treatment of acute rheumatism by the use of propylamine, which, he asserts, in 250 cases so treated was most successful.

The Reduction of Strangulated Hernia by the Use of the Aspirateur.

M. Dieulafoy, in drawing attention to this subject, quotes in its favour the success which has been already obtained, and that any danger is infinitesimal.

The wound of the intestine by the puncturing needle is so small that it cannot do mischief. This he confirms by 24 observations in various kinds of hernia—umbilical, crural, and inguinal. In none of these was there any inconvenience, and in those where subsequently an operation was had recourse to, it was hardly possible to find the point of opening. Puncture by the aspirateur is unquestionably the best aid to the taxis, and in 16 out of 24 cases of strangulated hernia, which had already resisted the taxis, together with chloroform, puncture by the aspirateur proved successful. This procedure has also proved advantageous in other hands.

Vicarious Menstruation.

M. Gayet, of Hôtel Dieu, records a curious case of vicarious menstruation in a young girl of 17, who had never regularly menstruated, yet every month she would lose for two or three days a considerable amount of blood from a fissure around either of the nipples. As soon as menstruation *per vias naturales* established itself this hæmorrhage ceased.

◆

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

February 10th, 1873.

Thomas Bryant Esq., F.R.C.S., President, in the Chair.

The President exhibited a drawing of a case of Periosteal Sarcoma of the Lower Jaw. The operation for removal was not difficult, but it was found necessary to disarticulate the jaw. The periosteum was separated, and the whole bone was taken out with great facility. At the end of five weeks the patient could masticate, and new bone was found to have been formed. The President also showed drawings of a case of Ivory Bone Growth of the Orbit. The patient was brought before the Society a few weeks ago. Mr. Bryant operated without difficulty, and removed a large mass of growth. The patient had done very well.

Mr. Jabez Hogg asked whether it would not have been best to let the orbit alone in this case?

Mr. Bryant agreed that, had he known the exact state of the parts before hand, he thought he would not have invaded the orbit. He thought the eye had been lost by not having stitched the eyelids, which he would do if another case offered.

Mr. Henry Smith then read a paper on the

TREATMENT OF HÆMORRHOIDS AND PROLAPSUS OF THE RECTUM BY THE CLAMP AND CAUTERY WITH THE RESULTS FURNISHED BY 300 CASES AND UPWARDS.

He commenced by referring to the first recorded cases of the treatment in question which were given to the Profession in the Lettsomian Lectures delivered before the Fellows in 1855. At that time the cases he had operated upon were only thirty-eight, but the results of these induced him to continue the treatment, as his experience increased, he gradually began to discard the use of the ligature, and he finally gave it up altogether, partly in consequence of some disastrous results in his hands, and partly from the excellent experience of the clamp and cautery. He now had operated on upwards of 300 cases and many of them of the most severe and formidable character both locally and generally, and he would lay fairly before the Society the results of his extensive experience. He would first refer to some of the objections which had been made against the treatment in question, some of which were quite frivolous, such an one for instance as had been urged against it by a well-known writer on diseases of the rectum, who affirmed that the operation was bad because more than an hour was consumed in performing it, the truth being that five, ten, or fifteen minutes were ample, as far as the actual operation was concerned according to the nature and magnitude of the disease. As regards the mortality which had occurred in his hands, he had already laid before the Profession two instances where death had taken place after the operation, and since that period a third fatal case has occurred in the instance of a gentleman in broken-down health, on whom he had performed a somewhat severe operation, severe vomiting set in and continued for thirty-six hours, and then intense jaundice followed, the patient dying on the fifth day. There was no *post-mortem* examination; and thus it was impossible to say whether death was caused by the chloroform or from some latent liver disease which had been aroused into activity by the operation. Only in two instances had anything like severe constitutional disturbance arisen after the operation with reference to hæmorrhage which was pronounced by some as a grave objection to the operation, he had not met with one single case where he had to plug the rectum, and only one instance where it was necessary to inject iced water. This immunity from bleeding he considered to be due to the great care with which he applied the cautery, using it very freely and with instruments of various shapes and sizes. He had never seen ulceration occur and persist for a length of time after the operation in any single case in his practice. The period of convalescence was short in the majority of his cases, the patients were walking about in a week. He had never known erysipelas or secondary abscess to occur after operation, a condition which occasionally gave great trouble after the use of the ligature, and the pain which ensued was generally at an end after two or three hours. The author then made some special observations regarding the mechanism of the instruments he used. Above all things it was most necessary that the blades of the clamp should have a perfect parallelism when they closed, and it was very important after the cautery had been applied, to unscrew the blades very gradually in case any vein should have escaped the influence of the cautery. There existed considerable difference of opinion as to the value of the non-conducting plates of ivory attached to the clamp, but he never thought of operating without them, and if the patient did not take chloroform they were absolutely necessary as they entirely prevented the pain of the cautery. In corroboration of his remarks as to the absence of bleeding and other points to which he had referred, Mr. Smith read letters from several of the old house surgeon of King's College Hospital, all of whom spoke as to the absence of bleeding in the cases they had attended.

In the discussion which followed,

Mr. Bond said, that when at King's he had seen both cautery and ligature used, and had left without any decided opinion on the subject. Subsequently, a case of a severe kind came under his notice, which had been treated by the cautery with great success. He had since then used the cautery in fifty cases very successfully and without hæmorrhage. He only used cautery in severe cases preferring ligature in simple cases. He never used the clamp without giving chloroform, and thought the ivory appendages were of no use. He preferred the clamp for prolapsus ani, and for some operations about the nymphæ.

Dr. Vine defended the ivory bars which he had invented. Ivory was a non-conductor, and prevented burning of adjacent tissues by conduction or from slipping of the cautery.

Mr. Allingham congratulated Mr. Smith on his success. He thought the clamp and cautery a good method of operation but that the ligature used as it ought to be was a better. In 3,000 cases operated on at St. Mark's Hospital by ligature not one case of pyæmia occurred, and tetanus in one case only. He had not had a single death in 500 cases operated on by ligature by himself. As regarded hæmorrhage perhaps he had not at first applied the cautery so freely as Mr. Smith had, but of late he had used the iron freely, and had had no hæmorrhage. If patients were sent out too soon after the use of the clamp and cautery, severe ulceration ensued inevitably. The susceptibilities of patients to pain differed greatly, but he thought there was no more pain after ligature than after the clamp. He thought the ivory wings of the clamp too broad and prevented the due removal of sufficient tissue. Free removal was absolutely necessary, and the pile should be removed down to the cellular tissue if a radical result was aimed at.

Mr. Alfred Cooper had had a great number of cases of hæmorrhoids under his care, and had used the ligature and the clamp about equally. He had never any reason to be dissatisfied with the ligature, but with the clamp he got severe secondary ulceration, and much greater pain was caused by the clamp than by the ligature. He had never seen hæmorrhage after the ligature; he could not understand how a patient could be cured effectually after three or four days. The plan of ligature introduced by Mr. Salmon, at St. Mark's, answered admirably.

Mr. Dunn corroborated Mr. Smith's statement as to the case they had seen together. The patient had been under the care of several eminent surgeons who declined to operate. He thought however the plan of ligature at St. Mark's was excellent.

Mr. Davy drew attention to Ambrose Pare's directions for avoiding the burning of skin. He thought the ivory was useful, the instrument often slipped when grasping the pile.

Mr. Wm. Adams asked whether with reference to the ulceration might it not be caused by using too hot an iron or by constitutional causes? The *écraseur* had given him satisfactory results in cases of disease of the rectum.

Mr. Wiblin (Southampton), as a provincial Fellow had listened to the paper and the subsequent discussion with much pleasure. In his earlier years he had used the ligature, but of late he had used the clamp which he much preferred, as causing less pain, and out of thirty-eight carefully recorded cases he got excellent results and had never had any hæmorrhage. He had not himself observed ulceration, and had been surprised at the rapidity of recovery.

The **President** for many years dealt with piles by means of ligature as taught at Guy's, but had not been quite satisfied. For the last eight or ten years he had used the clamp and cautery and had been well pleased with the results. He thought the iron should be freely used and that the ivory might facilitate this. The clamp was only a means to an end, and the treatment should be spoken of as by cautery than as by clamp. He always clamped each of the diseased portions before using the iron. The galvanic cautery answered admirably.

In replying, **Mr. Henry Smith** thanked the Fellows for the kind manner in which they had received and discussed his paper. He agreed with the President that the cautery was the principal part of the operation, it should be applied at a black heat. If there had been so much ulceration as had been spoken of, surely he would have heard of it, but as a matter of fact he had not heard of it. Mr. Allingham's remarks were valuable; as regarded pain, except in a very few cases he had not met with it, and this he attributed to the ivory plates for which suggestion he had to thank Dr. Vine.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, Feb. 11th, 1873.

T. B. Curling, F.R.S., President, in the chair.

REMOVAL OF A NEEDLE FROM THE HEART — RECOVERY OF THE PATIENT.

By Geo. W. Callender, F.R.C.S.,

Surgeon to St. Bartholomew's Hospital.

This is the history of a man who for nine days followed his ordinary occupation, in pain and discomfort, having a needle fixed in the tissues at the apex of the heart. On the ninth day, in consequence of his statement and in view of the pain he was suffering, an incision was made over the fifth intercostal space, and the broken eye of the needle was found on a level with the intercostal muscle. This extremity was seized, and the foreign body was withdrawn. The patient recovered without an unfavourable symptom. With this history the exact position of the needle in the wall of the chest is given, as also is that of its probable position in the heart; the movements of the foreign body, caused by those of the heart, are figured, and their measurements are added. Some remarks are made upon recovery and duration of life after somewhat similar injuries, and an appendix of cases is given in the form of a table.

CASE OF EXCISION OF THE KNEE-JOINT FOR DISEASE IN A WOMAN, ÆT. 53, WITH SUCCESSFUL RESULT.

By Frederick J. Gant, F.R.C.S.,

Surgeon to the Royal Free Hospital.

The object of this paper is to lay before the society the particulars of a case which may be regarded as a notable exception to the typical conditions of disease that are appropriate for excision of the knee-joint or other joints. The chief peculiarities are these: — The disease, chronic rheumatic arthritis of twenty-three years' duration, resulting in imperfect anchylosis, with partial dislocation of the leg backwards, corresponding malposition of the limb, and increasing tendency to displacement; the age of the patient, fifty-three years; excision as performed in relation to the state of the joint; firm union in seven weeks; complication of after-treatment by accidental attack of erysipelas affecting the whole limb without destroying the union; permanent result, and measurement of the limb five and a half months after operation.

In commenting on these particulars, the author was led to suggest the applicability of excision to a condition of disease which had not, hitherto, he believed, been submitted to the operation, and at a more advanced period of life, thus comprising a larger class of cases, although of exceptional character; in the present instance the age of the patient being the most advanced in which excision of the knee had hitherto been practised, or at least recorded.

Since completing the history of this case, the author has found one other case in which excision of the knee-joint was performed by Mr. Curling for chronic rheumatic arthritis, and with a successful result, the patient's age, however, being twenty-three years.

SUCCESSFUL CASE OF GASTROTOMY IN EXTRA-UTERINE GESTATION.

By Lawson Tait, F.R.C.S.,

Surgeon to the Birmingham and Midland Hospital for Women.

In the case of J. N——, æt. 27, retro-uterine pregnancy was diagnosed on September 23rd, the child having arrived at the term and died about the end of the July previous. The operation was performed on November 2nd, the section being much as in ovariotomy. After opening the sac the feet presented, and no difficulty was experienced in removing the child, except in extracting the head from the pelvis, in hich it was deeply packed, and where it had contracted adesions to the floor of its cavity. The edge of the wound in he sac was stitched to the edge of the peritoneal wound by a ontinuous suture, the peritoneal cavity being thus completely losed. The upper half of the parietal wound (its entire ngth being about seven inches) was closed by deep sutures. syphon drainage-tube was inserted deeply into the pelvic avity, and the whole was syringed out every eight hours ith a solution of sulphite of soda. A fœtid discharge issued om the cavity till about the eighth day after the operation, hen it became purulent, and was mixed occasionally with lacental *débris*. Pieces of detached placenta were removed ccasionally, together with fœtal hair which had become adherent to the internal surface of the cyst, and been detached from the scalp in removing the child, until November 29th, when the great mass of the placenta was removed. After this the cavity rapidly closed, the part in the pelvis being quite obliterated early in December, and the whole shut up by the end of the month, leaving only a small sinus. The patient had a severe struggle with hectic.

The chief peculiarities of the case are—the absence of any "false labour" previous to the death of the child; the leaving the placenta undisturbed; and the peculiar method of closing the peritoneal cavity, and leaving the parietal wound partly pen. To leave a communication between the cyst and the eritoneum is to run the gauntlet of pyæmia and peritonitis. losing the parietal wound entirely must lead to similar esults.

The operation, performed as in this case, would seem to ave no greater risks than ovariotomy, and it is certainly referable to leaving the cases to take their chance of discharging the misplaced fœtus by suppuration. If possible, he operation ought to be done near the term, and before the death of the child. If the latter condition cannot be obtained, the operation ought to be undertaken as soon after the death of the child as possible, to avoid the serious complications of adhesion between the fœtus and the cyst.

Mr. SPENCER WELLS thought the paper was of importance as showing that the placenta might be left and allowed to be discharged through the abdominal opening. This removed one of the great difficulties and dangers of the operation. From the account given, he thought that in this case the incision might have been made through the posterior wall of the vagina; it would have allowed more perfect drainage, and have imitated the natural process when the fœtus was spontaneously discharged, which was usually through the vagina or rectum.

Dr. HEYWOOD SMITH said there had recently been three such cases at the Hospital for Women, but all had proved fatal. In one case gastrotomy was performed and the placenta removed; the patient died from hæmorrhage and shock. In another, the placenta was left to be discharged through the abdominal opening—the patient died of peritonitis, which came on before the operation. He thought it was best to operate early during the life of the child.

Reports
ON
DISEASES OF THE THROAT.

Edited for the "MEDICAL PRESS AND CIRCULAR."

BY PROSSER JAMES, M.D., M.R.C.P.,
Lecturer on Materia Medica and Therapeutics at the London Hospital; Physician to the Hospital for Diseases of the Throat and to the North London Consumption Hospital; late Physician to the City and to the Metropolitan Dispensaries; Corresponding Member of the Academies of Medicine of Madrid, Lyons, Barcelona, &c.

LARYNGOSCOPY.

Demonstration—Various Modes, with patients, with drawings, with models—Auto-Laryngoscopy: several plans of examining and exhibiting one's own larynx.

To teach the art of laryngoscopy the professor may employ various methods—some of which are within the reach of every pupil, and will serve for self tuition and practice.

Unquestionably, the most efficient, as well as the most interesting plan of instruction, is to demonstrate upon living persons the natural form and colour of the various parts reflected in the laryngoscope, and already described, and to follow this by a series of demonstrations upon patients of the various diseases affecting these parts. For this purpose, however, the professor requires a large clinique, and undoubtedly the student who can avail himself of such instruction will make much more rapid progress than those not within its reach. Still, no one need despair. It is quite possible to acquire the art without an extensive clinique, though it must be much more slowly. The mere manipulation of the instruments will be readily acquired by any one from careful study of what has preceded, though it is much easier to learn from seeing them used.

As "practice makes perfect," the pupil will naturally feel diffident in his early attempts to examine a patient for himself. In a large clinique he will find a number of patients who are thoroughly accustomed to the contact of instruments with the throat, and who display the laryngeal image to its full extent without effort. The physician will naturally assign such cases to beginners, who consequently become rapidly familiar with the appearances we have already described, and being told the nature of the cases, do not fall into the errors they otherwise might. They have, therefore, nothing to unlearn.

The beginner may obtain a fair view by looking over the shoulder of the teacher while he is examining a patient for the purpose of diagnosis, and this is the best way to commence the study. It has been objected that the two observers do not see at the same moment exactly the same point, and we may admit that there is some force in the statement, but it is to be remembered that the part to be brought into view is not a mere point, but the image reflected in the whole surface of the mirror—an inch or more in diameter. As a matter of fact, we demonstrate daily in this manner not only the vocal cords in action, but diseases confined to small portions of the larynx, the diagnosis of which is oftened rendered distinct to those who have never previously seen the laryngoscope in use. A few lessons of this description will therefore save beginners much weary work in uncertainty, besides giving them sufficient confidence to begin to examine patients for themselves, which is the next object to be accomplished. At the Hospital for Diseases of the Throat there is every opportunity of thus learning laryngoscopy, and ample material for studying the practical applications of the art to the diagnosis and treatment of disease.

In the absence of such opportunities of practical instruction the learner will do well to set himself to work with drawings and models, then to practise auto-laryngoscopy, and afterwards to examine with the laryngoscope such of his friends as may be willing to permit it. These plans may be separately discussed. As to drawings, it has been shown in speaking of the theory of laryngoscopy, that the anterior part of the larynx appears at the upper part of the image on the mirror; while the posterior commissure is at the base, the former thus seeming the nearer, and the latter the more distant from the observer. This, which is the only inversion that really takes place, can be demonstrated by an ordinary toilet mirror inclined at a suitable angle, or what is still better, a laryngoscopic mirror may be used. For this purpose any of the laryngeal images engraved in these reports will suffice. A still better plan is to obtain a well made wax model of the larynx, and practise upon it in the same way.

Another step may be taken when either drawings or models are used, and it is particularly desirable in the latter case. It is for the student, having accustomed himself to see the parts in an ordinary laryngeal mirror by diffused day-light, to darken his room, and to practise with artificial light, just as if his model were a living patient. He may thus become completely master of his light, able to throw it on any point with the utmost facility, while he is learning the usual appearances of the laryngeal image. And he should remember that dexterity is of the first importance in laryngoscopy. Let him also thus practise holding the mirror with each hand, for he must aim at being ambi-dexter. Anatomical specimens may be carefully examined in the same way, and in all positions, and should these be not easily obtained, the larynx and trachea of a sheep, calf, or other animal, can always be obtained from the butcher. These parts should be read up at the same time.

All these plans are, however, only preliminary, and the pupil must eventually proceed to examine the living human larynx. He should not trespass upon the good humour of his friends until he has perfect command of his instruments, and is able to feel sure he will not produce any unpleasant tickling. By a little variation in the arrangement of his apparatus he may look at his own larynx in a looking-glass. This practice has been dignified by a distinct name—auto-laryngoscopy. He should become quite *au fait* at it, and we therefore proceed to consider it at length.

Auto-laryngoscopy (αὐτός λάρυγξ σκοπέω) is the art of examining one's own larynx. The pupil should practise it for the sake of acquiring facility in the use of instruments, and also as the best way of studying the anatomy and the physiology of the larynx. The movements brought about in breathing, in sighing, in vocalising, in coughing, in retching, in swallowing, can all be best observed on oneself. Moreover, he who has acquired complete control over his pharyngeal and laryngeal muscles can always demonstrate to others some of the most important facts brought to light by the laryngoscope. There are other reasons why the pupil should aim at being a good auto-laryngoscopist, and we shall therefore proceed to describe the various plans of examining one's own larynx.

The simplest method of all, when sun light is available, is to sit with the back to the light, so as to allow the rays to fall directly upon a small mirror held in one hand, while with the other, one of my rectangular faucial mirrors is introduced. The engraving (Fig. 2) shows this plan, which was adopted by Garcia, the first person who conceived the idea of studying the movements of the organ of voice in action (*a*).

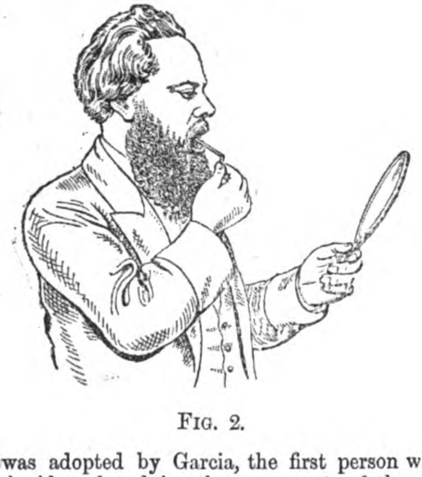

FIG. 2.

Artificial light may be employed in a similar manner. Another simple mode of illuminating the pharynx was suggested by Czermak, who placed a lamp as near as possible to the open mouth, and so held a small hand-mirror as to protect his eyes from the lamp, and permit him to see in it the image of the glottis reflected from the faucial mirror held in the other hand.

The pharyngoscope of M. Moura-Bourouillou (*b*) may be advantageously substituted for the simple lamp. In this instrument the rays of light pass through a perforation in the reflector, and fall directly on the faucial mirror. This instrument is also useful for other purposes. Those who employ my upright stand (Fig. 10) (*a*) as a support for the reflector, have only to supplement it with a common hand mirror to obtain the most convenient apparatus for auto-laryngoscopy by reflected light. Seated in the chair, which in simple laryngoscopy is occupied b the patient, the operator finds the lamp by his side, whil nearly opposite to him is the reflector. From this th rays of light fall upon his face, and with the hand mirro as a guide, opening his mouth, he easily takes the exac position to bring them to a focus in the fauces, where with the disengaged hand, he holds the laryngoscope Another person looking through the perforation in th reflector sees the laryngeal image. Indeed, two or thre can see it looking at the side of the reflector, and anothe person or two standing behind the operator can see th image at which he is looking in the hand-mirror.

An ordinary moderator lamp, with the reflector on stand, a faucial mirror and a hand-glass, thus furnish a simple and efficient apparatus for auto-laryngoscopy and demonstration on any convenient table.

This plan is so easy that I have heard of no difficultie The engraving (Fig. 24) taken from a photograph, show a demonstration to one person. It is obvious enough that others could also see, but it would be tiresome to photograph several, and the engraver has merely followed the original. On the lamp depicted a condensing lens is fixed, which, of course, increases the brilliancy of the light, as already explained.

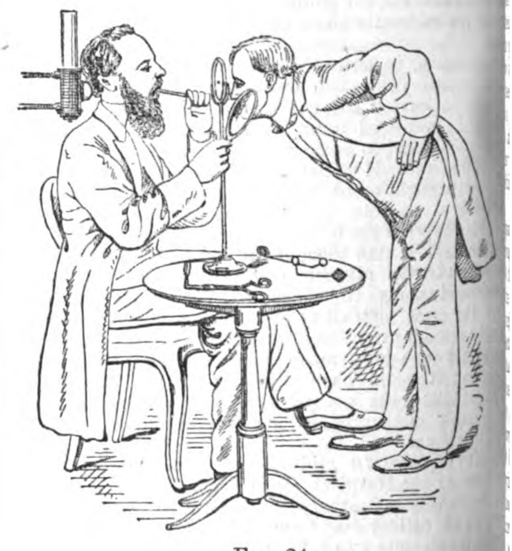

FIG. 24.

It may be thought by some that it is fatiguing to hold the hand-mirror steady. For prolonged demonstrations a little mirror can be supported on a jointed rod coming fro the stem of the stand. The beginner will, however, no regret the slight fatigue of a little practice by my method when he finds that it gives steadiness to his hands, an thus furnishes one of the best exercises in the manipu lations he will have to practise. He should therefor hold the looking-glass alternately with the left and righ hand, in order to acquire dexterity with each.

It has already been stated that Dr. Walker's globe con denser is furnished with a small plain mirror that make it available for demonstration. In fact, the addition of small plain mirror to any apparatus is all that is require Dr. Geo. Johnson has proposed another method, whic also has the merit of simplicity, but the image is perhap not quite so sharply defined as the light which falls o the faucial mirror is reflected from a plane mirror in fron of the operator instead of coming directly from th

(*b*) "Cours complet de Laryngoscopie." Paris, 1861.

(*a*) MEDICAL PRESS AND CIRCULAR, Aug. 28, 1872.

reflector. In his lectures already cited Dr. Johnson thus describes the plan :—

"Sitting at a table of a convenient height, I place a looking-glass at a distance of about eighteen inches in front of me, and a moderator or a gas lamp on one side of the glass, but two or three inches further back, so that the light may not pass directly from the lamp to the mirror. Now, with the reflector on my forehead, I direct the light as it were into the open mouth of my own image in the looking-glass; then, introducing the laryngeal mirror into my own mouth, I see the reflection of my larynx and trachea in the glass before me, and any one looking over my head or shoulder can see the image at the same time. This method therefore serves for auto-laryngoscopy and for demonstration ; in other words, the experimenter can, by this means, see his own larynx and show it to others."

"For beginners in the art of laryngoscopy this method affords a very useful means of training and practice. One of the chief difficulties at first is to keep a steady light in the patient's mouth while the laryngeal mirror is being introduced. Now, the student, after arranging his looking-glass and his lamp, may direct the light from the frontal reflector into his own open mouth in the looking-glass. This process differs scarcely at all from that which he will have to practice on his patients. Then, having learned to keep the light steady, he may practice the introduction of the faucial mirror, and he will soon see the interior of his own larynx and trachea. I have seen several of my Medical friends and pupils succeed in doing all this within less than half an hour of their first attempt.

"It is important to observe that in practising this method of auto-laryngoscopy both eyes may be protected from the glare of the lamp. The lamp is most conveniently placed by the side of the glass to the left of the operator. The right eye is then shaded by the lower margin of the reflector on the forehead, and the left eye may readily be shaded by one or two fingers of the left hand placed at the edge of the reflector. The fingers thus placed serve at once as a shade for the left eye, and a means of moving the reflector when the direction of the light has to be changed. If the experimenter desire to show his larynx to several persons at once, he can readily do this by having the mirror in front of him of small size, about three inches square, and fixed at a convenient height: the small flat mirror belonging to Czermak's auto-laryngoscopic apparatus may be used for this purpose. Thus, while two or three persons standing behind him can see the reflection of his larynx in the glass, two or three others standing in front of him, and looking over the top and by the sides of the glass into his mouth, may see the direct reflection of the larynx from the faucial mirror."

The only other method that need be mentioned here is that of Professor Czermak, which is well adapted for prolonged demonstrations. It requires, however, a special apparatus, and this has been improved by Weiss. It consists of a concave and plane mirror, supported on independent stems about a foot apart, in a manner to permit of motion in all directions, so that each mirror may be easily fixed at the necessary height and at any angle. The demonstrator sits before the plane mirror, into which he gazes. The concave mirror is about a foot further off, and so placed as to reflect the rays from the lamp into the mouth. The image in the laryngeal mirror can be seen by any one looking through or beside the reflector, and the image at which the demonstrator himself is looking in the plane glass can be seen behind him.

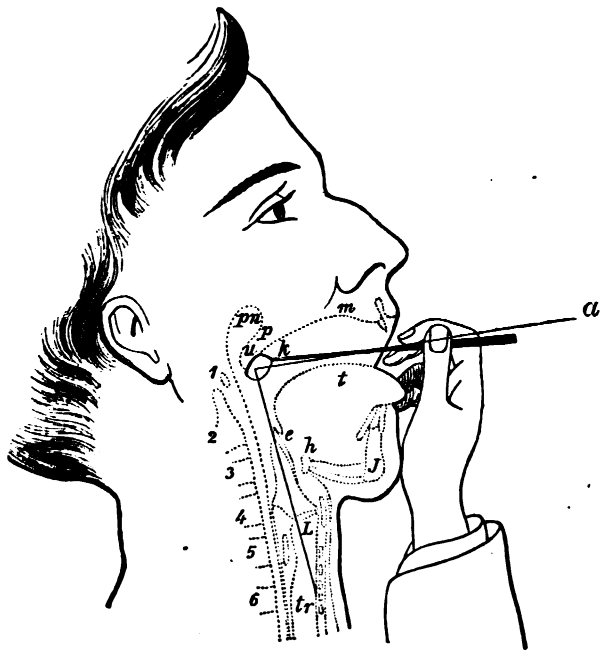

FIG. 25.

1 to 6, the cervical vertebræ; *u*, uvula: *L*, larynx; *e*, epiglottis; *tr*, trachea; *h*, hyoid bone; *t*, tongue; *j*, (lower) jaw; *m*, (upper) maxilla; *k*, laryngoscope; *p*, patella.

The theory of auto-laryngoscopy is, of course, the same as that of examining the larynx of another, and the practice consists in mere modifications of the position of the persons and the apparatus. The engraving (Fig. 25) may render the subject a little clearer. The laryngoscope being held *in situ* a ray of light represented as a straight line (*a*), is seen to fall upon it, and be reflected behind the epiglottis (*e*), and so down the larynx (*L*), impinging on the wall of the trachea (*tr.*).

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIERE, Publishers to the Academie de Médicine, Paris—post free in advance, £1 6s. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLMER and ROGERS; Baltimore, by Messrs. KELLY and PIET; Philadelphia, by Messrs. LIPPINCOTT and Co., and DR. BUTLER, post free in advance, £1 6s., about six and a-half dollars ; or direct from the Offices in this country for the same amount, by the new Post-office Order system.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 26, 1873.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

FOR a considerable period the Profession has evinced unusual interest in the Royal College of Physicians of

London, which is still looked up to by the public as the chief of our Medical corporations. Some time ago we entered fully upon the questions involved in the dissatisfaction often expressed respecting the mode of election to the fellowship of the College, and it is pleasant to know that the gentlemanly tone of the articles we published excited admiration in the highest collegiate circles. This, however, is no source of surprise since they proceeded from the pens of some of the most courteous of the Fellows. From that time attempts have been going on within the College to gain the full confidence of the Profession, and now under the able presidency of Dr. Burrows a scheme has been adopted that seems certainly a move in the right direction.

Without accepting it *in toto* we desire to express our approval of the spirit that seems to pervade the body of Fellows who, in the report of the Council which they last week endorsed, give utterance to their anxiety that, at the meeting or meetings held for nomination to the Fellowship, the claims of every member of the College should receive the most liberal consideration, and that no member should have the slightest reason for supposing that his claims to the Fellowship have been either overlooked or neglected. In order to effect so desirable an end, the following plan has been proposed and accepted :

1. That it be an instruction to the Council, in determining the fitness of members for nomination to the College for election to the Fellowship, to take into consideration—in accordance with bye-law, chap. xi, sec. 4—standing in the College ; academical honours ; distinction in literature or science ; professional eminence ; public appointments ; and social position.

2. That in each year, three months before the meeting of the Council for the nomination of members for election to the Fellowship, a notice to the following effect shall be sent to each Fellow.

> "It is the duty of every Fellow to assist in the nomination of fit and proper persons to the Fellowship. The duty thus devolving upon every Fellow has respect both to the College and to its members : to the College, since it is only by the election of fit and proper persons into the Fellowship that the College can be advantageously extended and perpetuated ; to the members, since every member ought to have full ground for believing that his claims to the Fellowship will not be overlooked or neglected. Your attention is, therefore, directed to the following regulation of the College.
>
> "Any Fellow of the College may propose, for the consideration of the Council for nomination for the Fellowship, any member of the College of at least four years' standing who has distinguished himself in the practice of medicine, or in the pursuit of Medical or general science or literature. The grounds of the recommendation must be fully stated in writing for the information of the Council, and be forwarded to the Registrar on or before the 24th June."

At the meeting of the Fellows last week the various points involved in the above report were discussed, but eventually it was adopted in the form we have printed it. In the original report two Fellows were required to nominate, or rather to recommend to the Council, but an amendment enabling one to do so was carried, and considering that after all the act is only formally mentioning to the Council the claims of a member it is certainly sufficient. The practice of naming a good man to individual councillors has never been quite in abeyance. No one can object to the propriety of any Fellow stating in writing to the Council as a body his view of the qualifications of any member.

We cannot, however, see that the Fellowship thus obtained will give full satisfaction to members. It is constantly objected that members are passed over, simply because no one thinks of them. They are doing good work in quiet, and as they would feel it a discredit to ask a Fellow to propose them they wait with such patience as they may, and often see their juniors pass before them.

It is difficult to see how this can be avoided without a radical change, and yet we hesitate to accept Dr. Williams's proposal for Fellows to propose, and the names to be suspended in the College for a time ; because a man so proposed but not elected on account of deficiency of votes might feel he had sustained a greater injury than if he had been passed by without publicity.

Still there is the objection to a small body like the Council discussing in secret the position of men they may not know or may not like, and the danger of mere gossip—so often untruthful—being acted on. This we may have occasion to return to ; but, meantime, it is aptly illustrated by the last paragraph of the Report, which is as follows.

> "The Council, in conclusion, begs leave to inform the College that, as an additional security against the claims of members being overlooked, it has adopted the following mode of proceeding :—
>
> "That in future the selection of members to be nominated to the College by the Council for Election as Fellows shall be conducted in the following way—
>
> "A month before the usual time of nominating, a preliminary meeting of the Council shall be held, at which a list shall be drawn up of those members who are selected for consideration.
>
> "During the interval between the meetings, the members of Council shall carefully inquire into the merits or disqualifications of those members whose names have been thus selected, so that at the final meeting of the Council for nomination it may be provided with more exact information than has hitherto been attainable."

MEDICAL LEGISLATION.

The following announcement in one of our London contemporaries, puts the relation of Mr. Hargrave and the Council of the College of Surgeons, Ireland, pretty plainly before the Profession.

> ROYAL COLLEGE OF SURGEONS OF IRELAND.
>
> Mr. Hargrave, the Representative of the College of Surgeons in the General Medical Council, to whom lately the Council of the College gave a gentle intimation that he should resign in favour of a more active representative, shows no intention of complying with this wish. How the Council will act in this difficulty it is impossible to say.

The Council of the College have acted in the difficulty, by unanimously requesting him to consider the desirability of resigning his present office of Medical representative on the General Council, a request which Mr. Hargrave very decidedly refused to entertain ; we can hardly call this a "gentle intimation," it was a unanimous one, and would have relieved the Council from an unpleasantness, which the uncertainty of a law opinion has but increased. Mr. Hargrave, having already retired from his hospital and professional duties, might fairly resign in favour as suggested of "a more active representative," particularly as in the present juncture of Medical and educational arrangements, a representative who could undertake active, and it might be laborious duties in forwarding the interest of Medical education is an essential

Hitherto, the question at discussion with the Council of the College of Surgeons has been, as to the illegality of Mr. Hargrave's election, and in consequence, the College not having a *locus standi* at the General Council, and that all acts in which Mr. Hargrave participates will be subject to the question of illegality ; but our contemporary takes the wider, and we might say more perhaps practical view, as to the desirability of having a "more active representative." This question should engage the earnest attention of the Council and the Fellows of the College without delay, these are not times for delaying or for imperfect representation. The Irish Colleges, excepting only the Queen's University, have framed a Conjoint Examination Scheme for submission to the Council, and time is specially valuable just now, as the "Faculty" remarks this week : "The Council as a public body has a great responsibility in doing nothing to settle this question, and to put the examination of general practitioners on a satisfactory and equitable basis. We have never approved the vague charges against the Council of doing nothing. But the entire arrest of its business as a regulator of Medical education and examination, and its helplessness amid the inaction or the resistance of the bodies of which it is composed, must ere long attract attention, and lead to more changes in the Act of 1858 than were dreamt of in 1870."

DEATHS FROM CHLOROFORM.

The recent death from the use of nitrous oxide has caused a profound sensation amongst those who were in search of a safe, or of the safest anæsthetic. Various influences have been assigned as the immediate cause of death. The heart has been supposed to be first affected, as the evidence given was "rapidity of pulse with diminution of its volume." The respiratory function has been supposed to have first yielded, as "the features appeared puffy, and the breathing became thick and stertorous ;" a piece of the gag was found wanting, and it has been even supposed that this made its way into the glottis. Unfortunately, no *post-mortem* examination was permitted, so matters must remain for ever in doubt.

As nitrous oxide has been advocated zealously by some as the safest anæsthetic, the anæsthetic question remains more disturbed than ever.

During the past week a death from chloroform took place in one of our Dublin hospitals, and, as in the case of this recent nitrous oxide death, and in many of those in which chloroform also proved fatal, the operation intended was a trivial one comparatively, and the subject apparently in good health. The quantity of chloroform used may be small also, and a few hurried whiffs may be sufficient to cause a fatal result. Thus, of 102 deaths from chloroform inhalation, Sanson found that 50 patients perished before the full effects of the remedy were produced. The case occurred at Sir P. Dun's Hospital, and was one of those unfortunately unanticipated accidents. The patient had the toes crushed accidentally, and amputation of some of them was about being performed by Dr. Bennett. The patient was, we understand, a comparatively young man, who had, up to the time, been employed at his business ; chloroform was being administered by the resident, when fatal symptoms ensued ; the operation had not as yet commenced, so that shock or hæmorrhage could have had no share in the fatal result. Full details of the accident will, we conclude, be communicated to some of our scientific meetings, together with a report of the *post-mortem* examination which may cast some light on the sudden nature of the accident. We have reason to know that a fatal case occurred in private practice during the last twelve months, where, though every precaution was taken, and a skilled chloroformist was entrusted with the administration, death ensued from the first few inhalations, and before a half drachm of chloroform had been used.

On the inquest, Mr. Forsythe, a pupil at St. Patrick Dun's, deposed that the deceased was suffering from severe injuries to the foot, and it was determined to subject him to an operation. Some chloroform was for that purpose administered to him ; almost immediately afterwards the deceased became violent, his pulse became weak, and then ceased, whereupon the administration of the chloroform was stopped ; the administration of the chloroform had not been continuous ; in consequence of the violence of deceased it could be administered only at intervals ; the galvanic battery was applied, but to no purpose. In reply to the solicitor who represented the next of kin, the witness said it was usual to examine the heart before administering the chloroform, but he had not seen this done on the present occasion. The jury found that the deceased died while under the influence of chloroform, and expressed their opinion that patients should be examined before being subjected to the influence of chloroform.

Another death is announced as occurring at the West London Hospital in the case of a woman, æt. 45, where, after one drachm had been used, signs of depression began to develope themselves.

In a paper lately read before the Bath and Bristol Association, Mr. Prichard, Consulting-Surgeon to the Bristol Infirmary, has drawn attention to such chloroform accidents. He remarks :—

"I had the misfortune to witness one fatal case in my own practice, where a man, æt. 49, healthy except for a diseased elbow brought on by injury, walked into the operation room and laid down on the table and died, after taking one or two inhalations of a drachm of chloroform, which had been poured on the sponge two or three minutes at least before. Death was clearly the result of sudden stoppage of the heart's action. Since that time there have been three deaths at our infirmary ; one since our last meeting in October ; and, I believe, besides, there have been two or three others in Bristol. There have been, however, in my own practice, and, I presume, in that of others, a number of marvellous escapes and terrible alarms, where the patients have ultimately recovered, but where the furious struggle made by the Medical men present for the preservation of life, and the excessive anxiety of the time, have been almost unbearable. Some present here, have been at such scenes with me, and have aided in the fight ; and, were it possible to weigh these dangers and calculate the risks, and gauge and compute their amount, and add the whole in due ratio to the deaths, we should have more to lament than even the dreadful and fatal score of one death per week in Great Britain, admitted recently."

Mr. Prichard illustrates the force of the latter remark by quoting a series of cases where the patients were in the most imminent danger, and indeed, were apparently dead, but where the strenuous exertions of the surgeons, assisted by the application of galvanism, &c., succeeded. He also draws attention to another class of cases, where chloroform has been administered, and where the patient died in a half conscious state some hours afterwards. Senior surgeons, who look back to the days when serious operations were performed without the use of chloroform, now begin to think that these lingering cases which more slowly prove fatal, were comparatively unfrequent in those times. Mr. Prichard draws his conclusion thus :—

> "These and numberless other instances prove that there are without doubt two sets of cases in which lives are endangered or lost, viz., where the heart's action is stopped, and when the breathing ceases ; and I have seen many instances of lengthened operations on persons severely hurt, where they have not died at once, but have lingered in a half conscious state for a day or two and then died. *I do not remember this class of case as having occurred, at any rate so frequently, before the days of chloroform*, and they are not unfrequently in reality deaths from chloroform, affecting the brain in patients so depressed by disease or accident that they cannot get rid of the drug."

We have seen a letter this week from Dr. Gavin, of Boston, in which he states that he observes with satisfaction, we are turning our attention to ether as the safest anæsthetic agent, he says,—"My connexion for years with a large metropolitan hospital, has afforded me a very extensive field for observation. I have administered ether in more than 5,000 cases, and besides have witnessed it given in as many more perhaps, without ever having seen any injury follow. In giving ether, one's mind is entirely free from any fear of fatal effects occurring." The latter observation of Mr. Gavin's is one which comes home to all practical surgeons, the distraction of attention, and anxiety as to the conduct and result of the chloroformisation, being the great incubus of the operator, whose undivided care should be given to the operation in which he is concerned.

For the last six months the advantage of the use of ether has been strongly advocated in this journal, and every day's experience tends to establish its claims to the important item of safety to life.

Notes on Current Topics.

Hydrate of Chloral.

In the minds of many practitioners some doubt has arisen as to the safety of a continuous exhibition of this valuable sedative, the report of the circumstances of a death after taking chloral tends to confirm the suspicion of its danger. The London Borough Coroner recently held an inquest on the body of a chemist. The deceased had, for the last six years, complained of his heart, and had for some time been taking hydrate of chloral to make him sleep. He took a dose on Tuesday night, and between eleven and twelve o'clock, as he was sitting smoking in his chair, his pipe fell from his hand. He became insensible, and before a doctor could arrive he was dead. The doctor was of opinion that death resulted from an overdose of hydrate of chloral, and the jury returned a verdict accordingly.

How they manage Herbalists abroad.

Two important cases relative to the sale of drugs in France have recently been decided. On the 11th of June, 1872, the Ninth Chamber condemned a wine merchant to a fine of 500 francs and 50 francs costs for having sold quinine wine, he not being a pharmacien. The wine merchant having appealed against this judgment, it came before the tribunal on the 5th of December, when not only was the judgment confirmed, but a second penalty of 500 francs with 100 francs costs was imposed upon him for having sold quinine wine at the Exposition of Domestic Economy.

On the 29th of November, also, the Ninth Chamber condemned a female herbalist to a penalty of 500 francs for having sold cod-liver oil ; and to 50 francs penalty and 300 francs costs for a sale of extract of cod-liver oil capsules. Upon appeal this judgment was confirmed a few days since.

We might learn a lesson from these decisions which would have salutary results, and tend to limit the careless and wholesale administration of medicines by unqualified persons.

The Effect of Increased Barometric Pressure on the Composition of the Blood.

The *Journal de Medicine and Chir. Pract.* has drawn attention to the experiments of Prof. Bert, who examined the effects of increased barometric pressure, as endured by submerged bridge-builders, divers, and pearl-fishers, and explained certain accidents common to such occupations, among others that of sudden paralysis following a rapid passing from very high to normal pressure.

An hypothesis of M. Bouchard, in his introductory thesis, has been justified by an experiment of M. Bert. It is quite possible, said M. Bouchard, that these accidents are due to a considerable disengagement of gas from the blood ; as effervescence is caused in gaseous water on its return to normal pressure when the bottle is uncorked. The presence of gas in the blood was demonstrated by M. Bert as follows : a cat, submitted to a pressure of eight atmospheres and rapidly removed from it, was almost immediately struck with paraplegia. Autopsy disclosed a non-hæmorrhagic softening of the spinal marrow and *gas in the blood-vessels.*

A practical conclusion from these investigations of M. Bert, applicable to occupations pursued under high pressure, is to supply, not pure air, but a mixture of air and nitrogen, in such a manner as to suitably reduce the pressure of the oxygen.

A Revolt against the Canadian Medical Council.

The Executive of the Medical Council of the College of Physicians and Surgeons of Ontario recently met in Toronto, at which meeting it was arranged that a deputation of Medical students would be received and their grievances duly considered.

Dr. Campbell, a homœopathic physician of the City of Toronto, who appears to be the chairman of the Council, as we are informed by the *Canada Med. and Surg. Journ.* received the deputation which presented written copies of the resolutions adopted by the students at their several meetings.

The resolutions submitted were substantially as follows :

1st.—That "the students feel that the Medical Act has signally failed in its main object,—viz., in securing protection to regularly licensed practitioners, inasmuch as the country is literally flooded with quacks, druggists, and others, with questionable qualifications, who, in open defiance of the presumed intention of the said Medical Act are openly practising medicine, surgery, and midwifery, to the detriment of legally qualified practitioners. It is therefore resolved that the Medical Council be requested to take action to secure for the Profession the protection so much desired."

2nd.—That "the students consider that the fees charged by the College of Physicians and Surgeons are exorbitant, request that the said fees be reduced."

3rd.—That "the students demand that the questions hereafter propounded to candidates be handed them in printed form."

4th.—"That in the event of the Medical Council failing to comply with the above demands, the students shall then take into consideration the advisability of not presenting ourselves at any future examination of the said Council."

Ulster Medical Society.

The Seventh Meeting of this Society was held at the General Hospital on Saturday, the 15th inst., when the following communications were made :—

Dr. John Moore introduced a patient with Obliterated Brachial Artery from Wound in Axilla; also a case of Irreducible Dislocation of Thumb.

Dr. H. S. Purdon introduced a patient the subject of Grave's Disease.

Dr. Brown read Notes of a case of Peritonitis following the Introduction of a Tangle Tent into the Uterus. The case resembled one of strangulated hernia, a tumour existing in the groin, which, on operation, was found to be an obliterated hernial sac.

The President exhibited an obliterated hernial sac from a case of obstructed bowels, in which the operation for hernia was performed; also a specimen of *post partum* pelvic abscess, opening into ilium.

Dr. McCrea read Notes of a case of Idiopathic neuritis.

Brice Smyth, M.B., read Notes of a case of Puerperal Convulsions.

Dr. Charles exhibited and described the following recent specimens :—

1. Fracture of the Acromion and Coracoid Processes of the Scapula.
2. A *vas aberrans* of the arm.
3. A remarkable extra Capsular Fracture of Neck of Femur.
4. Calcified Arteries of back of Leg.
5. Bony Growths on the outer end of the Clavicle.

The Board of Trinity College, Dublin, and its Professor of Anatomy.

The decision of Sir Joseph Napier and Dr. Battersby, Q.C., the acting visitors of the University on the dispute between Dr. McDowel and the University authorities, deferred until Saturday week was delivered on that day.

It will be recollected that the Board maintained that it had a right to require Dr. McDowel to resign his surgeoncy of the Richmond Hospital, and that it was also empowered to set aside a part of the dissecting-room fees, payable to Dr. McDowel, for the endowment of Dr. MacAlister's Professorship of Comparative Anatomy. Dr McDowel joined issue as regards these assumed rights.

The Visitors have decided, as regards the question of the dissecting-room fees, that the Board was entitled to deal with them as they proposed. They were, however, divided in opinion on the competency of the Board to insist on Dr. McDowel's resignation of the Richmond Hospital and, in consequence, he remains undisturbed in his occupancy of that office. The result of this verdict is that the allocation of a part of Dr. McDowel's emoluments to the payment of the Professor of Comparative Anatomy will be persisted in, while, on the other hand, Dr. McDowel will remain undisturbed as surgeon in the Richmond Hospital. There is, we believe, no practicable appeal from this decision. It does not yet appear what course Dr. McDowel will pursue in reference to Sir Patrick Dun's Hospital. Under the provisions of the School of Physic Act he is, *de facto*, as a Professor, bound to act as surgeon to that Institution if permitted to do so. By the Amendment Act power was given to the Board, if a professor should refuse or fail to perform the duty, to appoint a deputy-surgeon and pay him the hospital fees. At the time that the Board thought fit to remove Dr. McDowel from the surgeoncy of Dun's they availed themselves of this power and appointed Dr. Thomas E. Little in his place. This arrangement, however, ended with the vacating of the Professorship by Dr. McDowel and, having been re-elected for a new period, he again becomes, *ipso facto*, surgeon to the hospital. As the Board of Sir Patrick Dun's Hospital have neither rescinded their condemnatory resolution nor granted the enquiry which he demanded, Dr. McDowel naturally objects to undertake duty in the hospital, and asks the Board to relieve him of it and appoint a deputy as before. It remains to be seen whether they will comply with his request.

Cod-liver Oil and Chloral.

This combination is recommended by the *Boston Medical and Surgical Journal.* The oil is rendered less nauseating, sleep and appetite are improved, and nocturnal sweating of phthisical patients is checked by it. One part of crystallised chloral may be added to 9 of oil.

The Medical School of Montpellier.

The French Government has closed this school entirely owing to disturbance among the students. It appears that some student addressed a letter to the Mayor of Carcasonne, protesting against a judicial sentence pronounced against him. During the subsequent deliberation of the Academic Council, the students assembled and interrupted the lectures which were being given, and repeated the disturbance next day. Hence the closure of the Medical and Pharmaceutial Schools.

Woolwich Workhouse—Lights again.

From a report of a late meeting of the Woolwich guardians we find Mr. Tuffield again distinguishing himself. It is a remarkable instance of the force of habit to find in Mr. Tuffield—notwithstanding our kind and humane suggestion to him on a former occasion, to learn ere he attempts to teach—that he still is "wiscious." In the present instance, amongst other things, he asked the master—who, "of course, knows everything"—"if he had ever heard of champagne being ordered in *any* workhouse before." The master replied, "he had not." We sincerely hope the master is only one of the "dunce master" class, and no more. Let us enlighten this master, and observe that champagne has been and is given even in London workhouses. According to the Woolwich paper, this Mr. Tuffield complained that one inmate had been having champagne of the finest brand, at 3s. 6d. a pint, and said if it were necessary as a stimulant in cases of delirium tremens, the cheaper quality would do. They might pay as much as 14s. a bottle for champagne; *but 17s. a dozen was enough for Medical purposes (!).* It was shameful to provide champagne out of the rates for a young man, reduced to his present state by vice, whilst large numbers of poor and virtuous ratepayers could scarcely get the bare necessaries of life.

Medical Women.

THE Russian Government has authorised the Academy of Medicine of St. Petersburg to accept a sum of 200,000 francs (£8,000), offered to it by Mme. Lidie Rodstvenna, for the foundation of Medical lectures for women.

The Proposed New Charity.

UNDER this title several letters have lately appeared in our columns to which we would direct particular attention. The abuses of hospitals are notorious enough but cannot be brought home too thoroughly to all classes. The idea of lawyers working for nothing, and fighting for the chance of doing so, as physicians and surgeons do, once expressed, is a genuine *reductio ad absurdum* of the system of Medical charities. What say Sir C. Trevelyan and Mr. Jodrell to this correspondence?

THE authorities of the University of Oxford have definitely secured the services of Professor Max Müller; he will not now go to Strasbourg.

THE Principal of Glasgow University, Dr. Barclay, died on Saturday of bronchitis, at the ripe age of eighty-one. He was admitted to be one of the greatest linguists in the United Kingdom.

HIS Excellency the Lord Lieutenant of Ireland has, we learn, appointed Dr. Philip C. Smyly, surgeon to the Meath Hospital, to be surgeon to His Excellency, in the room of Dr. Hatchell, who has been appointed His Excellency's physician, along with Dr. Nedley. Dr. Smyly has, we believe, been in attendance on His Excellency for some affection of the throat, and his advancement is the reward for his success in its treatment, and a recognition of his high surgical standing.

Mr. Smyly has long occupied a rank in the Profession which entitles him to the honour which has been conferred on him, and we regard his advancement as a gratifying proof that, in the selection of Court honours, surgical rank, and high professional status, are once again recognised as claims to such distinctions as the Viceroy can confer.

STUDENTS' COLUMN.

LECTURES ON HUMAN ANATOMY.

By WALTER RIVINGTON, M.S., Lond., F.R.C.S., En

Surgeon to the London Hospital and Lecturer on Anatomy
London Hospital Medical College.

LECTURE III.

Peculiar Vertebræ—Atlas—Axis and Seventh Cervical— Ninth, Tenth, Eleventh, Twelfth Dorsal—Fifth Lu Tabular View of the Peculiar Vertebræ—False Ver Sacrum, and Coccyx—Tabular View of Anatomy Sacrum—Origin and Meaning of the terms Coccy Sacrum.

GENTLEMEN,—There are certain of the True Ver which deviate from the differential characters assign the last lecture to their respective regions, and require rate notice. Among the Cervical Vertebræ, the First, Second, and the Seventh have special features; among Dorsal, the First, the Ninth, the Tenth, Eleventh Twelfth, and among the Lumbar, the Fifth.

The *First* and *Second Cervical Vertebræ*, or as the popularly termed the *Atlas* and *Axis*, are specially mo for the performance of the movements of the head. articulations between the Atlas and the Skull, the posterior or nodding movements of the head are eff by the mode of union of the Atlas and the Axis, the ro action of the head is secured.

The *First Cervical Vertebra* is called the *Atlas*, bec supports the Head. Atlas was the son of Iapet Clymene, and brother of Prometheus, who stole fi Heaven. His father was one of the Titans, whom joined in making war on Jupiter. For this, when the were subdued, he was condemned to bear Heaven head and hands, and he is represented in statues, as ing beneath the burden of the rounded firmament punishment of Atlas appears severe, but inasmuch father of Atlas was the Son of Heaven and Earth, it consisted in the filial penalty of being compelled to his grandfather, whom his brother Prometheus had In the early ages of Greece, such ordinary fact dressed in a splendid garb of fiction. The Grecian of Heaven is but a deification of human existence, an the cares and joys of human life, so the structure of below is reflected by the wayward wit of man, on above" (*a*). Imagination reigned supreme before the of genuine history; and in the infancy of science, entered freely into the realm of fact. Anatomy for exception to this statement. The classical fathers dry rigid anatomy have enriched its nomenclatur words conveying poetic allusions, an example of wh before us in the comparison of the first Cervical Ve to Atlas, and of the Head to the Heavenly Sphere.

The *Second Vertebra* is called the *Axis*, because as its main feature a tooth-like process, called the *Odonto Process*, which acts as a pivot around which the At Atlas can easily turn. The particular purpose of these two Vertebræ is the key to its conformation.

The *Atlas* is usually described as forming a *Rin* posed of two *Arches*, and two *Lateral Masses*, one o side, placed between the *Arches*, and, *bearing the Ar Processes*. Each *Lateral Mass* forms one-fifth of the Ri *Anterior Arch* a fifth, and the *Posterior Arch* the remainin fifths. The Atlas presents both *negative* and *positive* ters. Its *negative* characters are the absence of a *Body*, absence of a proper *Spinous Process*. Its *positive* cha are its resemblance to a *Ring*, its possession of two an *anterior* and a *posterior*, and of two strong proce *Lateral Masses* for articulation, with the Condyles Skull above and the Axis below, its *Notches* placed its *Articular Processes*, its special arrangements for co the Odontoid Process, and playing round it. These ters should be read by the light of the functions of the

The *Body* of the *Atlas* is in reality fixed to the the Odontoid Process, and nothing remains to repres body but a small *tubercle* on the anterior arch. The *Sp Process* is reduced to a *tubercle* on the posterior arch, is not wanted for the attachment of any prominent mus

---

(*a*) "The Place of Ancient Greece in the Providential Order of World." P. 25. Gladstone.

(*b*) The term Odontoid is from the Greek words ὀδοὺς, a tooth, εἶδος, form.

and its projection backwards would have interfered with the movements of the head. Both *Arches* are thin, and the slenderness of the *Posterior Arch* is peculiar to man. The *Articular Processes* are specially modified. They are placed further forward so as to transmit the weight of the Condyles of the Occipital Bone to the Bodies of the Vertebræ below. Their superior surfaces form cups, raised at their two extremities and outer margin, converging towards each other, covered in the recent state by cartilage, and having a direction in the centre upwards, backwards, and inwards.

The *Inferior Surfaces* are concave or flattened in the dry bone, and work on the superior articular processes of the Axis when the head is rotated. The muscles which perform this movement are attached to the *Transverse Processes* of the *Atlas*, and act upon them. To give the muscles greater power and leverage, these processes are made considerably longer than in the other Cervical Vertebræ. They are large and strong, and perforated by a continuation of the foramen for the Vertebral artery ("vertebrarterial canal" of Owen.)

In consequence of the great length of the Transverse Processes, they "act like the bars of a capstan," and the horizontal motion between the Atlas and the Axis "is very easily and briskly performed." (South.)

To confine the *Odontoid Process* in its place, a ligament stretches across between the *Lateral Masses*, dividing the *Ring* of the *Atlas* into a smaller space in front, for the *Odontoid Process* and a larger space behind for the Spinal Cord. The *Inner Surfaces* of the *Lateral Masses* are rough and tubercular for the attachment of the *Transverse Ligament*. If you look at the *Odontoid Process* itself, you see that towards its base it is more slender than it is above, and presents a constriction. This is intended to enable the Transverse Ligament to clasp the process, and keep it securely in the socket formed for it by the ligament and the anterior arch of the Atlas. In order to permit a freer and a smoother play of the Atlas, two oval *facets* are placed on the *Odontoid Process* above its neck, one in front, and one behind. The *anterior facet* corresponds to a similar facet on the posterior surface of the anterior arch of the Atlas, the *posterior facet* corresponds to the Transverse Ligament. A small Synovial Sac is provided for each of these little joints for the purpose of giving ease to the rotatory motions here accomplished.

The *Notches* of the *Atlas* are placed behind the advanced articular processes. On the upper surface of the *Laminæ*, is a groove, which may be converted by a bridge of bone into a canal, for the transmission of the First Spinal or Suboccipital Nerve. This conversion into a canal or hole is the ordinary disposition in many Apes, in Carnivora, in Rodents, in Ruminants, and other Mammals. In Man, the Vertebral Artery, after leaving the continuation of the "Vertebrarterial Canal" through the Transverse Process, lies in the groove over the first nerve. In animals who have a complete foramen in the Arch, the Artery may or may not accompany the Nerve. In Ruminants, the Artery is separate, and passes between the arches of the first and second Vertebræ. Lastly, observe the large size of the Foramen behind the Transverse Ligament, and especially its lateral extension, which is designed to guard against compression of the Spinal Cord, when the Atlas rotates round the Odontoid Process, and the space for the Cord is of necessity diminished in size.

The *Axis*, *Vertebra Dentata*, or *Pivot Vertebra*, is a stoutly built bone well fitted for transmitting the weight of the head from the Atlas to the bodies of the Vertebræ below. Rising up perpendicularly from its strong *Body*, is the *Odontoid Process* already partly described. We have noticed the constriction at its base, and the facets in front and behind on the expanded portion above, to facilitate the movements of the Atlas. We notice now, that it becomes pointed at its summit, and that the sides are rough and inclined for the attachment of some important ligaments, which connect it with the bone above the Atlas—the Occipital Bone.

The *Articular Processes* are peculiarly arranged. The *Superior* are separated from the *Inferior*, and placed by the side of the Odontoid Process, presenting above, two slightly sloping surfaces on which the inferior articulating processes of the Atlas glide. The lower processes are placed behind the upper so as to be in a line with the articular processes of the other Cervical Vertebræ. Springing from the Axis by two roots, one from beneath the superior, and the second from above the inferior articular surface, is a short non-bifurcated *Transverse Process* turned downwards as well as outwards. It is perforated at its base by a *Foramen* for the passage of the Vertebral Artery. In many specimens this foramen is fully entitled to the name of a canal, for it is longer than any of the other foramina, and makes a distinct bend in its course, passing upwards and then curving outwards.

The *Pedicles* are broad and strong. The *Laminæ* are thick and strong. The *Spinal Foramen* is very large. The *Superior Notches* are shallow, and placed behind the superior articular processes; the *Inferior Notches* are in front of the inferior articular processes. In some of the lower Mammals, as in the Ruminants, the aperture for the Second Cervical Nerve is a canal, which passes through the lamina of the Axis near its upper (*i.e.* anterior) border. The *Spinous Process* is characteristic; it is large, rough, very strong, deeply channelled on its under surface, bifid and tubercular. The reason for its size and strength is, that it gives attachment to several muscles, and among others, to the important little muscles which pass from it to the Transverse process of the Atlas to perform the rotatory movements. In many Mammals the Spinous Process of the Axis is greatly developed, being extended both forwards and backwards, and overlapping the spines of adjacent Vertebræ.

Looked at as a whole, the Axis may be compared to the upper part of a human figure with the arms stretched out in front, and the hands sloped and touching each other along the borders of the thumb and index finger. The Odontoid Process is the head and neck, the Superior Articular Surfaces are the sloping shoulders. The elbows are in the situation of the Inferior Articular Surfaces, the forearms and hands in the position of the Laminæ with a deep grove between the palms.

The *Seventh Cervical Vertebra* is called the *Prominent Vertebra* (vertebra prominens), on account of the length of its *Spinous Process*, which has acquired dorsal characters, and is thick, tuberculated at the extremity, and not bifurcated. It is an elegant process, nearly horizontal in direction, and attaches *inter alia*, the *Ligamentum Nuchæ*—a mere rudiment of a structure which is of great importance in the brute family.

The *Transverse Process* sometimes supports a Cervical Rib; sometimes it is destitute of a *Foramen*. Occasionally this Foramen transmits the Vertebral Vein, and in very rare instances, the Vertebral Artery. It is generally smaller, I believe, than the foramina in the other Cervical Vertebræ.

In the Gorilla, most of the Cervical Vertebræ merit the description of prominent Vertebræ, for the spines of the third, fourth, fifth, and sixth are very long. In the Chimpanzee and Orang, they are long, but not so long as in the Gorilla. The Anthropoid Apes usually possess undivided Spinous Processes, so that the bifurcation of the spines of the Cervical Vertebra, is a character essentially human.

The *Dorsal Vertebræ* are distinguished from each other by the small surfaces on their Bodies for the Heads of the Ribs which they support, by their relative size, by the comparative obliquity of their Spinous Processes, and by the position of the articular facets for the Tubercles of the Rib on the Transverse Processes.

The *First Dorsal Vertebra* has one and a-half facets on each side; a whole facet above for the First Rib, and a demi-facet below for the Second Rib.

The *Second*, *Third*, *Fourth*, *Fifth*, *Sixth*, *Seventh*, and *Eighth* have each demi-facets on each side above and below. The *Ninth* has generally a demi-facet above, and the *Tenth*, *Eleventh*, and *Twelfth*, each whole facets for the corresponding Ribs.

The *Upper Surface* of the *First Dorsal Vertebra* is lipped and elongated transversely, its *articular surfaces* are oblique, its *Spinous Process* thick, long, and horizontal. Thus it shows a transitional character between the Cervical and the Dorsal Vertebræ.

The *Eleventh Dorsal* acquires some features of a Lumbar Vertebra. The *Articular Surfaces* for the Ribs are chiefly on the *Pedicles*; the *Transverse Processes* are very short, tubercular, and without facets for the Ribs. Its *Spinous Process* is short, nearly horizontal, and has a tendency to bifurcation.

The *Twelfth Dorsal* is very like the Eleventh, and still more like a Lumbar Vertebra. The *Inferior Articular Process* is turned outwards; the Transverse Process is short, tubercular at its apex, and destitute of a facet.

The *Fifth Lumbar Vertebra* possesses a body about a fourth thicker in front than behind. The *Spinous Process* is not quite so long as the others that it may not project inconveniently in the hollow of the back. Its *Laminæ* are less deep. The *Inferior Articular Processes* are widely separated. The *Transverse Processes* are larger and thicker than those of the other Lumbar Vertebræ, and attach ligaments connecting the last Lumbar Vertebra with the Sacrum and the Ilium. It may serve a useful purpose if we follow our favourite plan and make a

TABULAR VIEW OF THE PECULIAR VERTEBRÆ.

I.—PECULIAR CERVICAL VERTEBRÆ.

	Atlas.	Axis.	Vertebra Prominens.
	Consists of two arches, anterior and posterior, with two lateral masses, one on each side, between the Arches.	Very strong, deep, prolonged downwards anteriorly. Marked in front by a ridge and two depressions for Longi Colli. Supports Odontoid Process. This Process is slender at the base or neck, and bears an oval facet in front and behind. Summit pointed, sides above inclined and rough for Cheek Ligaments.	
Body..	Absent, united to the body of the Axis as the Odontoid Process.		Has Cervical characters.
Arch — Pedicles ..	Unite in front, and form an Anterior Arch, which is marked behind by a facet and in front has a tubercle.	Broad and strong.	Ditto.
Arch — Laminæ ..	Unite behind and form Posterior Arch.	Thick and strong.	Ditto.
Foramen	Atlas forms a ring divided into two parts by Transverse Ligament. The anterior smaller division is for Odontoid Process; the posterior or true Foramen for Spinal Cord is very large.	Very large.	Ditto.
Transverse Process	Long and strong for rotatory muscles (Inferior Oblique). Perforated for Vertebral Artery. Not bifid.	Short, non-bifid. Long curved Foramen; two roots, one from beneath Superior, the other from above Inferior Articular Processes.	Characters intermediate between Cervical and Dorsal. Posterior division is true transverse process; anterior represents a rib, and does not always bound Foramen, which is small.
Articular Processes	Articular facets are supported by the Lateral Masses.	Articular Processes separated.	
Articular Processes — Superior	Form large cups for Condyles of Occipital Bone	By the side of the Odontoid Process; sloping downwards and outwards.	Cervical characters.
Articular Processes — Inferior	Concave or Flattened.	Behind the upper.	
Spinous Process ..	Reduced to a Tubercle.	Thick, strong, large, bifid, deeply grooved beneath.	Gives name to Vertebra from its prominence. Long, tubercular, acquiring Dorsal characters. For attachment of muscles keeping up the head.
Notches	Superior, behind lateral masses. Inferior, behind lateral masses. Superior Notches represented by grooves on Laminæ for Vertebral Artery and Suboccipital Nerve.	Shallow, placed behind Superior Articular Processes. In front of Inferior Articular Process.	Cervical characters.

II.—PECULIAR DORSAL VERTEBRÆ.

1st	Body lipped above, bears on each side a whole facet above for 1st Rib, a half facet below for 2nd Rib.
2nd, 3rd, 4th, 5th, 6th, 7th, 8th, have common dorsal characters	Demifacets on each side above and below. Each articulating with four Ribs, two on each side.
10th, 11th, 12th..	Single whole facet on each side for 10th, 11th, 12th Ribs respectively. Facets further back, partly or wholly on Pedicles.
11th, 12th	No facets on Transverse Processes. Transverse Processes short. Spinous Process short, like Lumbar; tendency to bifurcate. Acquirement generally of Lumbar characters.

III.—PECULIAR LUMBAR VERTEBRA.

5th ..	Body thicker in front than behind by about one-fourth. Smaller Spinous Process. Laminæ less deep. Large and thick Transverse Processes. Inferior Articular widely apart.

(*To be continued.*)

◆

THE IRISH COLLEGE OF SURGEONS AND THE MEDICAL COUNCIL.

We have reason to believe that the Council of the Irish College of Surgeons at its last meeting had under consideration the position in which it is placed, in reference to the approaching meeting of the Medical Council, and the Conjoint Examination Scheme which will be then under discussion. As it appears to the Council impossible under all the circumstances to replace Mr. Hargrave by an efficient delegate, an anxiety is felt that their views should, at least, be represented in some form. Accordingly it was proposed to draw up a statement of the Council on behalf of the College, and entrust it to Mr. Hargrave, with instructions to submit the views therein contained, and none other, to the Medical Council. The majority of the College Council, however, decided—and, we think, wisely—not to recognise Mr. Hargrave as their representative in any way, but to forward the statement of their views direct to the President of the Medical Council, and leave Mr. Hargrave to act as he chooses on his own behalf.

This means of communication, though, perhaps, the only one open to the Council, is a melancholy alternative on which to hang the interests of surgery in Ireland. We trust that the Profession and the Medical Council will not forget that, when the case of Irish Medical education comes to be tried, it must be heard without an advocate for the chief surgical corporation of Ireland, and will, therefore, allow a margin in the argument for what might be said if the Irish College of Surgeons could speak.

Literature.

PROCEEDINGS OF THE PATHOLOGICAL SOCIETY OF LONDON FOR THE SESSION 1871-72.

(*Continued from page* 9.)

No. 9, by Dr. Crisp, is a case of "Fatal Strangulation from the twisting of a portion of the Colon." All cases of this kind are of interest, for the causes which lead to the fatal result are very numerous, leaving the diagnosis most obscure. The explanation, too, of the state of the parts does not seem to be even yet settled, for one party says there is spasm, and another paralysis, and this speaking of the same morbid parts. But we wish more particularly here to state our conviction that operative proceedings ought to be employed more than they are. Now that such formidable operations can be performed—and with a great amount of success—as the removal of the ovary, there would surely be no valid objection to opening the abdomen in a case of obstructed bowel, and where all ordinary means had failed; yet, we can scarcely call to mind any one—if we recollect right we must except Trousseau—who has so acted. In the case before us an operation would certainly have held out a reasonable hope that life might so have been saved, for there were no signs of inflammation present, and the lesion consisted in the turning over of a portion of the descending colon on itself. We cannot pursue this subject further here. It is, however, due to the author to state that, he speaks of the question of the propriety of operating.

In connexion with the last case we may notice No. 12, by J. S. Bristowe, M.D., as being of a somewhat similar nature. In this instance the stricture arose from a malignant growth in the upper part of the descending colon. The trocar was here used to draw off the air, very shortly after which the patient sunk; and on making a *post-mortem* it was found that perforation of the bowel had occurred, as the result of an ulcer on the mucous surface, and that the wounds caused by the trocar had nothing whatever to say to the sudden death. This case will well repay perusal, and is very well detailed.

Nos. 14 and 15, both by C. Murchison, M.D., are examples of hydatid tumours of the liver and peritoneum. In each operative proceedings were used, and with temporary benefit. In one of these Mr. Spencer Wells opened the abdomen, and removed between three and four pounds of hydatid cysts, leaving still some behind. This patient remained much relieved for nine months, when the disease returned, and she died.

No. 21, by W. R. Gowers, M.D., is entitled "Cancer of the Liver." Both the lungs and lumbar glands were also involved. The liver weighed 19½ pounds, and presented the disease known with us in Dublin as Farre's tubercle. It would seem as if the lumbar glands were the parts first engaged, for the patient, a female of 30, had suffered from pain, referred to the left thigh and knee for some time before she spoke of anything wrong in the abdomen. The pain, too, was accompanied with marked wasting of the muscles. This state of things is the special reason for which we notice the case at all, as such symptoms would be quite capable of leading to an erroneous diagnosis.

No. 24, by W. Moxon, M.D., is entitled "Syphilitic Disease of the Liver suppurating, and opening a Bile Duct." This is another example which we think may very fairly be explained in a different point of view from what the author advances. Well may he add that it is a new way in which syphilis shows itself in this organ. For ourselves we think the disease was malignant, and that the reasons given for a contrary opinion are not valid. But we cannot pursue the subject further here.

Diseases of the Genito-Urinary Organs.

We find we will not be able to do more than give the headings of a few of the more interesting cases detailed in this section. No. 1, by W. Moxon, M.D., advances the idea that the state of the kidney known to result from long-continued stricture may get well, and he advances a case in proof of this. The suggestion seems to us a valuable one, and we believe we have seen it actually occur. No. 3, by W. H. Dickenson, M.D., for John Hawkes, M.D., is an example of the horse-shoe kidney, found in the body of a lunatic. This state had, of course, nothing to say to the mental state of the patient. No. 7, by John Wood, is entitled "The Pelvis and Genital Organs of an Adult Hæmaphrodite." This truly remarkable specimen was taken from the body of a person who had passed as a female, and had been married for many years. The body was 5 feet 9 inches in stature. The case is too long for insertion here, but its perusal will well repay the reader. The case is particularly well given, and equally well illustrated by engravings. The conclusion at which the author arrives is, that the individual was more of a man than a woman. No. 8, by T. Holmes, is an example of melanosis of the penis. It was growing eight years when the patient was admitted to hospital. We notice the case as we believe it to be rare.

Diseases of the Osseous System.

Many of the cases in this section will interest the surgeon, those more particularly connected with the excision of the head of the femur, and detailed by John Gay and T. C. Jackson. In one of these cases we observe that, after excision, the surgeon had to amputate the limb, and did so with complete success. The reader will also find a very elaborate account, by J. Hutchinson, of two cases of "chronic rheumatic arthritis," the disease so well known and described in Dublin. No. 12, by W. Tay, is entitled "Lymph Adenoma of the Ileum, Sternum, Rib, Pleura, Lungs, Heart, and Kidneys." We only notice this case on account of the name given it, and we must say we do not see what advantage arises from these new names. If the texture of the diseased parts differs from malignant disease, let this be stated, and then we can understand a new name being applied. But as we read the case it was one of ordinary malignant disease, where new names tend only to add to the difficulties of the subject, and in no one way, as it seems to us, add to our knowledge. No. 13, by J. Croft, is entitled, "Osteo-Sarcoma of Tibia; recurrence in lower end of femur; amputation at hip-joint; recovery." This is a case of much interest. We should be glad to hear whether the patient still lives, for we presume the word "recovery" applies to the patient getting over such an operation as amputation at the hip. The tumours were pronounced to be medullary cancers. Nos. 15 and 16, by H. Arnott and W. Adams, are each examples of multiple exostoses. These are very interesting cases, and will well repay perusal, though too long for further notice here. We may just observe that one was a girl of 18, and the other a boy of 10 years of age.

Tumours.

In this section we notice several cases of great interest. The first, by W. Squire and J. F. Payne, is entitled, "Lymphadenoma." It is a case of unusual interest, is given at great length, and particularly well detailed. It has one drawback, however, that we are left in the dark as to its nature. There is not a word as to whether the disease was or was not malignant, nor does the long name given it add to our knowledge in any way; still, the case is about the most remarkable in the entire volume. No. 2, by F. Churchill, M.B., is entitled, "Fatty Tumour Simulating Ranula." It occurred under the tongue in a man of 86, was twenty-one years growing, and was successfully removed. A tumour of this nature in such a locality must, we think, be very rare. No. 6, by T. B. Peacock, M.D., is entitled, "Case of Intra-

Thoracic Tumour causing effusion into the right pleural cavity, obstruction of the descending cava and pressure on the recurrent nerves, and involving the heart." This case is of interest, and though too long for insertion here, will well repay perusal. Under the idea that the tumour might be syphilitic, hydridate of potash was given. Our experience does not afford any grounds for supposing that such a case could, by any possibility, have been due to this poison. On the contrary, each and every symptom pointed to malignant disease. Yet the author seems to have a kind of doubt of this, and uses the following words:—"It (the tumour) may very probably have been soft and medullary when fresh and would, in that case, have been formerly described as a medullary cancer." How it is changed by the fact of not being fresh we do not know, or how calling it "lymphadenoma" alters the matter for the better we do not see; but, for ourselves, we have never read a more unequivocal case of soft cancer. No. 7, by W. Jay, is a case of "Fibrous Tumour removed from a Child's Arm." The tumour, which was the size of a small adult's fist, grew from the inner side of the arm, close to the axilla. The growth was pendulous, and was removed with success. The child was nine months of age. No. 12, by S. Jones, is a case of "Pendulous Parotid Tumour." This is an interesting case. The tumour was more than three pounds weight, and was removed from a lady of 58. Twenty-eight years previously a tumour had been removed from the same region by the late Mr. Travers. Except from its weight the second tumour had caused no inconvenience till fourteen months before its removal, when bleeding took place, and recurred so often as to affect very seriously the health of the patient. It was removed with success. In this instance the tumour seems to have been of a very diversified character. No. 14, by W. Rivington, is entitled, "Blood Cyst connected with a Nerve in the Left Axilla." Much obscurity hangs over this case, nor does the examination of the tumour seem to have thrown a clearer light on it. The committee appointed to examine it say—"We are unable to determine from the specimen the way in which the cyst originated, but presume that it is merely a blood-clot which has become encapsuled." No. 18, by T. Holmes, is a case of "Epitheliomatous Tumour of the Scalp." The tumour, when first removed, was merely a wart. It rapidly grew again, and as rapidly became an ulcerated fungus. This was entirely removed, but within a week the patient—a man of 64—showed grave constitutional symptoms, under which he sank. Extensive arachnitis of the brain was found, and also serious diseases of the kidneys, the latter being most probably the starting-point of the fatal issue.

Diseases of the Ductless Glands.

The two cases given in this section are each of interest, being examples of disease of the supra-renal capsules; the first being complicated with phthisis, occurred in a boy of 18, and the second, having no pigmentation of the skin, occurred in a woman of 39. Of the nature of this affection there would seem to be still much doubt. For ourselves we believe it to be some modification of the strumous diathesis; but, it would be out of place to say more of this here.

Under the head of "Miscellaneous Specimens" at the end of the volume, we observe two worthy of a short notice. One, by J. B. Sanderson, M.D., is entitled, "Preparations Showing the Results of Certain Experimental Inquiries relating to the Nature of the Injective Agent in Pyæmia." We cannot notice this subject further here than to say that there are reasonable grounds for hoping that these experiments will throw light ultimately on the important subject of pyæmia. We may just observe of it that the process in man seems to be of a very much more acute character than in the lower animals; nor are we aware that in the human subject tubercles or tuberculous matter are a result of the pyæmic processes, similar to what is seen in the lower animals. The second communication, and the last we feel called on to notice is by E. Crisp, M.D., "(Tubercle in the Common Fowl after Vaccination." T also will be found a very interesting paper, and w worthy of perusal. It bears, too, on the last commu cation.

We have now finished our brief notice of a few of more striking subjects detailed in the volume. A whole it affords a wide field for adding to our knowled of morbid anatomy, and as such we can strongly reco mend it to the favourable notice of our readers,

Correspondence.

THE PROPOSED NEW CHARITY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR,

SIR,—The communications following my first letter to y advocating a legal charity, have hardly taken the view I tended to present, and have surprised me not a little, yet t illustrate the difficulty of finding brains for other people. is really as increditable as it is funny, that the gentlemen have disported themselves in your columns should imagine to be seriously advocating the self-destruction of the legal fession, and not to have perceived that my object was to i tute the "*reductio ad absurdum*," and draw attention to sad contrast between the two professions, both containing of talent and learning, but one being rich and powerful other poor, and at present powerless. It is the nature o Englishman to enjoy, or at least to put up with being sat by somebody in power, and he is not generally very carefu inquire how that power is obtained, having an uncomforta lazy feeling that so long as he is sat upon by somebody, th must be all right. As he was at one time the most pri ridden being in the world, so now is he the most lawyer-ri and groans lazily and helplessly under the sway of an rheumatic, stiff-jointed, legal yoke. Possibly at some f time, when quite sick of the tortures of the law, he ma himself, and seek a more beneficent sway from the d but that time I should imagine is far distant.

In the meantime would it not be well to inquire h times gone by, the other two professions respectively ob undisputed power in the body politic, the answer is so that it would occur to any one—simply by co-operati pulling together. The Church, by acting in union, r power almost boundless; then, as always follows, she that power, and consequently fell, remaining ever sin state of chronic bickering and disunion.

The law having succeeded to her inquisitorial and tyr sway, is even now attempting to set her house in order, ing lest a powerful, and not too delicate hand should in order for her. But now to take ourselves, we have at the other end; when was the time known that d didn't disagree.

"A Law Student" is quite right; I do "look at ho and see most plainly, possibly more plainly, than he "ho Profession is injuring itself and others;" my object is n pull down a sister profession, but to drag my own out slough of despond into which it has gradually subsided. idea looks gigantic, but it is not so. If one would only a moment, mankind could get on very well without la I should hardly like to suggest how we should do wi priests, except to notice that a large number of us do well without them at present, but without doctors equ as some one has said of love, "the world simply could round." I do not wish to be understood to advance the t that the actual terrestial rotation would be much af either by the absence of medicine or amativeness; but I if either or both were to fail us, our population would soon come to serious grief. Verily, is not the Medical fession grievously like a strong, good-tempered cart- who plods along his daily work, sorely tormented by owners with all the power, but without the intelligence t his vast strength in a manner more profitable to himself others.

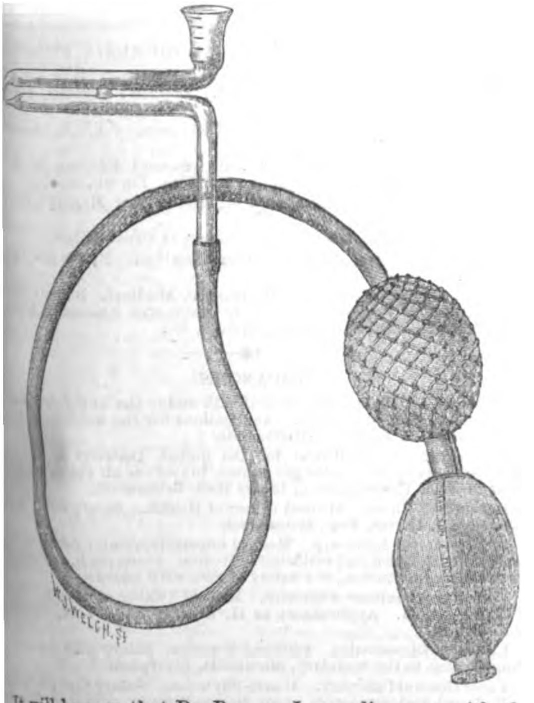
When I was at school I sat next a little boy, and we wrote in our copy-books, "Union is strength." He lever little boy, and became a lawyer, while I entered a Pro-ssion which left its copy-books at school, and has never igested, and possibly never will digest, the labours of common nse it might there have learnt, but didn't.

I have the honour to be, Sir,
Your obedient servant,
A. W.

Inventions.

A NEW ATOMISER.

Messrs. Maw, Son, and Thompson have sent us the following woodcut of the simplest spray-producer ever made, and hich they propose to call after its inventor, Dr. Prosser ames. It was exhibited, they tell us, by Dr. James nearly wo years ago, at the Medical Society of London, and met ith great approval. Some improvements have since been ffected in it. Its great merit is its cheapness, which places t within the reach of all classes.



It will be seen that Dr. Prosser James dispenses with the ogether. The liquid to be atomised finds its way by vity from the cup, which holds the quantity to be used h time, and is there converted into spray by the air coming n the other tube when the bellows are used. The tubes made of glass, and can therefore be replaced for a few ce in case of accident, as Messrs. Maw are prepared to sell e tubes without the bellows. They have been already y largely used, and have given universal satisfaction. Of rse the atomisers can be made in vulcanite or silver, but s is clean and cheap. Dr. Prosser James refuses to allow atomiser to be patented, his only object being to put a p and efficient article at the command of all patients, n the poor. In this wish he has been seconded by Messrs. w, Son, and Thompson, who will supply them at the west possible price.

Parliamentary Intelligence.

SELF-MUTILATIONS IN CHATHAM CONVICT PRISON.

Mr. R. Fowler asked whether it was the intention of the Government to take measures to diminish the number of accidents, self-mutilations, and other injuries, reported from Chatham Convict Prison, showing that out of an average of 1,692 convicts in the prison at the last return, there were 1,725 admissions to the hospital, and 20 deaths, also an increase of abscesses from 153 to 270, of ulcers from 98 to 247, contusions from 316 to 487, including 17 cases of prisoners purposely fracturing their arms or legs, by thrusting them under waggons or engines; and 24 cases of purposely self-inflicted wounds which the prison surgeon reported to be "of so severe a character that amputation was immediately necessary, in most cases, as the limbs were so mangled as to preclude any hope of recovery."

Mr. Bruce replied that in 1871 there was an increase of this practice in some of the prisons and a decrease in others; he admitted that the increase at Chatham was great and startling.

Medical News.

Royal College of Physicians of London.—The following gentleman was duly admitted licentiate of the College on the 30th day of January, 1873:—

Hope, Samuel Wilson, Berlin House, Dulwich.

The following gentlemen were admitted licentiates on the 18th day of February, 1873:—

Atthill, William Eyre Bleunerhassett, Muswell Hill.
Brown, James, Leeds.
Chicken, Rupert Cecil, Guy's Hospital.
Groves, Henry Joseph Firth, 36 Oakley Crescent, Chelsea.
Hopper, Arthur Richard, 31 Arundel Street, Strand.
Richmond, Onslow Robert, Hornsey.
Snell, Simeon, 26 Belitha Villas, Barnsbury.
Williams, Henry, Guy's Hospital.
Zimmerman, Richard, M.B., St. Thomas's Hospital.

The following candidate, having passed in Medicine and Midwifery, will receive the College Licence on his obtaining a Qualification in Surgery recognised by the College:—

Pilkington, William Binns, Crawshawbooth, Lancashire.

Indian Medical Service.—The Military Secretary, India office, presents his compliments to the Editor of the Medical Press and Circular, and begs to enclose a list of the Candidates for Her Majesty's Indian Medical Service, who were successful at the competitive examination in London in August, 1872, and at Netley in February, 1873, and who have undergone a course of instruction at the Army Medical School, together with the total number of marks obtained at the examinations in London and at Netley:—

S. Brereton, Dublin, London, and Paris, 5,459 marks (has obtained the Herbert Prize.)
M. D. Moriarty, Dublin, 5,120.
G. Price, Belfast, and Dublin, 5,118.
E. Bovill, London, 4,965.
B. O'Brien, Cork, 4,645.
G. A. Dundas, London, 4,315.
H. W. Hill, Edinburgh, 4,290.
Z. A. Ahmed, Calcutta, Glasgow, Edinburgh, and London, 4,280.
E. Levinge, Dublin, 4,265.
A. N. Rogers-Harrison, London, 4,133.
W. A. G. Gilligan, Dublin, and Edinburgh, 4,045.
L. Beech, London, 3,915.
W. E. Griffiths, London, 3,881.
D. H. Cullimore, Dublin, 3,861.
H. P. Esmonde-White, Dublin, 3,770.

London International Exhibition, 1873.—The fourth meeting of the Committee on Surgical Instruments and Appliances, took place last Tuesday week at the Royal Commissioners' Offices. The members present were Mr. Cæsar H.

Hawkins, F.R.S., in the Chair, Dr. P. Allen, Mr. R. Brudenell Carter, Mr. W. White Cooper, Dr. H. J. Domville, C.B., Dr. Arthur Farre, F.R.S., Mr. J. Hilton, F.R.S., Mr. Liebreich, Mr. J. Luke, F.R.S., Dr. A. G. Mackay, Mr. J. Marshall, F.R.S., Mr. T. W. Nunn, Dr. W. S. Playfair, Mr. R. Quain, F.R.S., and Mr. E. Saunders. The Committee, after transacting the general business of the meeting, considered the applications, more than sixty in number, which had already been received. They adjourned until Monday, the 17th of March, the date of receiving the goods being Tuesday, the 11th of March next.

University of London.—The following resolution, recently passed by the Senate, will take effect at the Matriculation Examination of June next :—That Greek be no longer compulsory on candidates at the Matriculation Examination, but be ranked as optional with French and German ; so that it shall be sufficient for any candidate to pass in *any one* of these *three* languages.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this request.

All communications intended for insertion must bear the name and address of the writer; not necessarily for publication, but as a voucher of good faith.

Subscriptions in the United States.—A correspondent has drawn our attention to the fact, that some of the houses in the United States are charging the enormous figure of 15 dollars per annum (more than £3) for supplying this Journal to different parts of the States. We beg, therefore, to state that we shall be happy to supply the same regularly, post free, per annum, if paid in advance, for considerably less than half this amount, viz., six and-a-half dollars (about £1 6s. 0d.), either direct from our offices in this country, or through our recognised agents in the United States.

Law respecting Periodicals, Newspapers, &c.—1. Subscribers who do not give express notice to the contrary, are considered as wishing to continue their subscriptions. 2. If Subscribers order the discontinuance of their periodicals or newspapers, the publisher or publishers may continue to send them until all arrears are paid up, and Subscribers are held responsible for all numbers sent. 3. If Subscribers neglect or refuse to take the periodicals or newspapers from the office to which they are directed, they are held responsible till they have settled their bills. Sending numbers back, or leaving them in the office, is not such notice of discontinuance as the law requires. 4. If Subscribers remove to other places without informing the publisher, and their periodicals or newspapers are sent to the former directions, they are held responsible.

Dr. W. Robert Smith, Huddersfield.—We shall be happy to inspect your MS.

Dr. D. W. T., Liverpool.—We never promise notices of any works we have not seen.

Royal College of Physicians of London.—Dr. Robert Liveing will lecture on "Elephantiasis Græcorum," on March 7, 12, and 14, at 5 o'clock. Members of the Profession admitted on presentation of their cards.

R. W., Westminster.—Quite out of our province.

Winter.—*Savants* prophecy some very hard weather for the next fortnight or three weeks. Confirmatory of this is the large flocks of wild fowl which have migrated southward during the past few days.

Cantab.—At the Fellowship Examination in 1874 a Fellowship will be obtainable by adequate proficiency in Natural Science (new foundation). The examination, which will take place in the end of September or beginning of October, will be chiefly in chemistry, physics, and biology, and in the subjects of any papers that may have been sent in. Candidates must send in to the examiners (care of Mr. Trotter) on or before the 15th of May, 1874, any papers which they may have published containing original observations or experiments, or discussions of scientific questions, or any similar matter in manuscript. The papers may be on any branch of natural science which is not strictly Medical. They must be accompanied by a statement as to what portions of the matter are claimed as original, and of the sources from which the rest is derived, so far as they are not explicitly stated in the paper itself. Candidates will be liable to be examined in the subjects of their pape and in matters connected with them, or in the branches of science which they refer. This Fellowship will be open to all Bachelors Arts, Bachelors of Law, and Bachelors of Medicine of the Univer whose standing after their fresh degree does not exceed three y Candidates who are not members of the college must send their na to the Master of the College on or before the 15th of Septem accompanied by certificates of good character. Further informat will be supplied on application to the Rev. Coutts Trotter, Tutor Trinity.

Glass Eyes.—These artificial aids to beauty have recently ca considerable annoyance to their wearers. At Boston some detecti wanted a man named W. H. Johnson, who had a glass eye. They fo such a person, and he was the wrong gentleman. They found anot W. H. Johnson in Salem, also with a glass eye, and he, too, proved be an innocent man. They then received a telegram from Newbu port, stating that a W. H. Johnson with a glass eye had been arres there, and he likewise proved to be the wrong customer. There i fourth W. H. Johnson with a glass eye, somewhere, and the Bost authorities are naturally anxious to make his acquaintance.

To the Editor of the "Medical Press and Circular."

Sir,—I cannot imagine how any person who knows Tuffield acknowledge him to be a Rev. gentleman. He is not. When he came to the town of Woolwich, he was employed by a man na Barnaby, a candle maker, in High Street, Woolwich, and Tuffield employed to empty grease tubs, &c. He once had a chandlers in the New Road, Woolwich. He sold that, and now styles hi Rev. T. Tuffield.

A Ratepayer of Woolwich, and a Lover of Fair Pl

Advertisements.

[ABRIDGED PROSPECTUS.]

THE CONTRACTORS' AND ENGINEERING AGENCY ARE AUTHORISED TO ISSUE

THE BANAGHER DISTILLERY COMPANY, King's County, Ireland (Limited).—Capital £100,000, in 20,000 Shares of £5 each. Incorporated under the Companies' Acts of 1862 and 1867. Deposit, 10s. per Share on application. Payments, 10s. per Share on allotment, £1 per Share in two months. Future calls as may be required; no call will be made without giving one month's notice.

DIRECTORS:

Alderman Sir Sills John Gibbons, Bart. (late Lord Mayor of London), Calvert Buildings, 17 Southwark Street, S.E., Chairman.
Captain C. A. Armstrong, J.P., Mount Carteret, Banagher, King's County, and Junior United Service Club, London, Resident Director.
George Battcock, Esq. (Battcock and Son), 4 Carlton Street, S.W., Director of the Mutual Life Office, London.
Charles John Todd, Esq., 18 Bread Street Hill, London, Director of the Mutual Life Office.
Francis Albert Waller, Esq., Prior Park, Roscrea, County Tipperary, and Banagher, King's County, Malster, Resident Director.

BANKERS:

Messrs. Barclay, Bevan, Tritton, and Twells, Lombard Street, London.
The Provincial Bank of Ireland, and its Branches.

SOLICITORS:

Messrs. Thomas White and Sons, 11 Bedford Row, London.
Adam Mitchell, Esq., Parsontown, and 4 South Frederick Street, Dublin.

MANAGER AND OPERATIVE DISTILLER: William M. Peacy, Esq.
ENGINEER: John J. Hogan, Esq., 7 Bridgefoot Street, Dublin.
AUDITORS: Messrs. Quilter, Ball, and Co., Moorgate Street.
SECRETARY (*pro tem*): Charles F. Griffin, Esq.
Temporary Offices: 4 Westminster Chambers, Victoria Street, S.W.

In the event of no allotment the deposits will be returned without any deduction.

This Company is established for the purpose of making Whiskies of superior qualities.

The head office of the Company will be in London, and the Company under the management of the London Directors, while the Distillery will be under the supervision of the resident Directors, gentlemen of position and experience.

No promotion-money will be paid.

Practical and careful estimates of the cost of the plant required have been prepared, and after making full allowance for working and all incidental expenses, the Directors feel assured that there will be a profit of from 20 to 25 per cent. to divide among the Shareholders.

Prospectuses and forms of application for Shares may be obtained at the Office of the Company, and of the Bankers or Solicitors; and priority of application will be first considered. Application for Shares to be sent through the Bankers of the Company; for safety in transmission, cheques should be crossed Messrs. Barclay, Bevan, Tritton, and Twells, or the Provincial Bank of Ireland.

BILLIARDS.—BENNETT AND CO., Surrey Street, Strand, sell more Billiard Tables than all the London makers combined, and have ruined the enormous profits of the ancient, high-priced firms. Purchasers save £20 to £35, and warranted a better table.

BILLIARDS.—For SALE, BENNETT AND Co.'s CHAMPION MATCH TABLE, elegant in construction, guaranteed the finest and most perfect ever manufactured. Only used for five matches. Price, 55 guineas, with ten years' warranty.—Surrey Street, Strand.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—Dr. ROBERT LIVEING will LECTURE "ON ELEPHANTIASIS GRÆCORUM," on March 7th, 12th, and 14th, at FIVE o'clock.

Members of the Profession will be admitted on presentation of their cards.

By Order.

The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements, from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

The scale of charges is as follows:—

Seven lines and under	£0	4	0
Per line afterwards	0	0	6
One quarter page	1	5	0
Half-page	2	10	0
One do.	5	0	0

When advertisements are given for a series of insertions, a very considerable reduction from the above scale is made.

☞ Advertisements for Insertion in this Journal must be at the OFFICE, on SATURDAY, by Two o'Clock.

THE MIDLAND RETREAT

(Near Maryborough, on the Great Southern and Western Railway.)

FOR THE RECEPTION AND TREATMENT OF THE INSANE, and of persons suffering from a disturbed state of the Nervous System, under the direction of Dr. JACOB, Physician to the Maryborough District Lunatic Asylum (260 patients), Surgeon to the Queen's Co. Infirmary, &c.

THE ESTABLISHMENT consists of separate and commodious residences for the reception of Ladies and Gentlemen. Each situated on extensive grounds, with large, well-enclosed gardens. They are handsome, well-furnished country residences, where the patients enjoy the comforts and indulgences of a private house. Restraint is not, under any circumstances, practised, and the closest attention is paid to the medical treatment and general health of the patient.

APOTHECARY ESTABLISHMENT FOR SALE.

TO be SOLD by PRIVATE CONTRACT, the INTEREST of the REPRESENTATIVES of the late H. P. SMITH, Esq., L.A.H., in that Shop and Premises in the main street of the town of Strabane, in which the business of an apothecary has been successfully and extensively carried on for a great many years. The business has been conducted since the death of Mr. SMITH by his Representatives, and is at present in a flourishing condition. The receipts and sales of the business for several years past have averaged a sum exceeding £600 each year.

This is the only apothecary establishment in Strabane, a town of 5,000 inhabitants, 18 miles distant from Derry, and surrounded by a populous and rich district of country.

The stock of medicines at present on hand is large, and the shop fixtures are excellent, being almost as good as new.

The premises are held by lease for 30 years from the 1st November 1866.

Proposals by intending purchasers will be received by the undersigned up to the 1st of March next.

Strabane, 28th Jan., 1873. THOMAS LYLE, J.P.

THE STEWART INSTITUTION FOR IMBECILES AND LUNATIC ASYLUM, LUCAN.

PATRON:—H.R.H THE PRINCE OF WALES.

This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £25 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote.

Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c., can be had at the office,

40 MOLESWORTH STREET, DUBLIN,
W. O'NEILL, Secretary.

ECCLESTON SQUARE.

VITIATED AIR.

No. I.

(A PAPER READ BEFORE THE ASSOCIATION OF MEDICAL OFFICERS OF HEALTH, FEB. 15, 1873.)

BY C. MEYMOTT TIDY, M.B., F.C.S.,

Joint Lecturer on Chemistry and Professor of Medical Jurisprudence at the London Hospital, Medical Officer of Health and Food Analyst for Islington, Master of Surgery, &c.,

We have heard of late a great deal about water, I hope I shall be excused drawing your attention to another of the elements scarcely second in importance.

As water may contain and, at times, perhaps does contain a little of everything that is soluble, air may contain and does contain at times a little of everything that is volatile.

Probably, some of the very earliest analyses that were ever conducted were examinations of air. The history of air analysis is tempting, but it would lead me too far astray to attempt it.

A uniform mechanical admixture (uniform owing to the principle of diffusion) of nitrogen and oxygen, 20·81 parts of oxygen by measure in 100·0 parts and 79·19 of nitrogen constitutes an ordinary sample of atmospheric air freed from carbonic acid and aqueous vapour. But other things are invariably present as well as these, *e.g.*, carbonic acid, aqueous vapour, nitric acid, ammonia, carburetted hydrogen, sulphuretted hydrogen, sulphurous acid; some, or all of them.

The action of the oxygen of the air was soon determined. It was the life gas of the animal—it was the life gas of the flame. That the body is a furnace is no modern conception nor is it any mere poetical idea. Carbonic acid is the product of combustion be it candle, gas, or muscle. The whole difficulty to the early chemists was solved, and the solution commended itself because of its extreme simplicity. The purity of the air, the salubrity of a district, they all agreed, depended on the amount of oxygen being large, and the amount of the carbonic acid small. So the sanatarian taught; and the earlier experimenters gave us results that confirmed these views. At one time 18 per cent. only of oxygen was found, at another 24 or 25 per cent. But we know now how valueless their analyses were, because of the excessively imperfect methods they adopted. As time goes on great improvements are made in analysis, and at once a new creed is promulgated that no matter where the air is taken from, be it a densely populated town or country lane, an open field or a crowded theatre, the amounts severally of the oxygen and carbonic acid are uniform; and yet again as time advances, and knowledge increases, more perfect analyses are made, and this view is proved incorrect. Variations, by still further improved methods of analyses are noted both in the oxygen and the carbonic acid, small, I admit, but still easily detected by the chemist.

Some at this story may be led to ask what is truth? It is but one illustration of the progress of science, and progress means life.

The ordinary estimation of the nitrogen, oxygen, and carbonic acid of air is simple enough. We may employ a bent tube known as Cooper's tube, absorb the carbonic acid with caustic potash, determine its quantity and then absorb the oxygen by the addition of pyrogallic acid which becomes oxydised by the oxygen of the air in the tube. The remainder is nitrogen; and taking care to make the necessary corrections for temperature, pressure and aqueous vapour in the determination of the volumes of the several gases, the analysis is complete.

But I certainly think though all this is easy enough but very little practical good results from such examinations. We are all of us familiar with what we call an offensive stuffy air, and Dr. Angus Smith, has of late thrown a great deal of light on a subject which needed a good deal to enlighten it. I am afraid we should not, as a rule, make out much loss of oxygen by the most accurate of methods in our close atmosphere.

No doubt, in all air analysis it is very advisable to estimate the carbonic acid, whilst the estimation of the oxygen is scarcely worth the trouble. The estimation of the carbonic acid is easily done and with very considerable accuracy too, by the degree of turbidity resulting from its action on baryta water. I even blow for a second (as Dr. Letheby once pointed out) in this bottle containing perfectly bright baryta water and you will notice it instantly becomes clouded. In estimating the carbonic acid I employ these small tubes with glass bottoms. Taking a bottle containing a known quantity of air, I pour into it about 20 septems of baryta water which is the quantity my little tube holds, shake it up thoroughly for a few minutes, pour it into the tube, and estimate the carbonic acid by the degree of turbidity as shown by comparison with similar tubes holding the same quantity of baryta water, and containing known quantities of carbonic acid. With a little practice it is very easy, I find, to decide equal turbidities and to calculate quantities with at any rate relative if not absolute accuracy.

But it appears to me that we shall find an excellent test of the purity of the air, by the estimation of the ammonia that it contains. This is easily done by the Nessler fluid which, as you all know, turns of a brown colour with ammonia, the depth of the discoloration depending on the amount of ammonia present in the liquid under examination. It is perfectly certain that when air contains above a certain amount of ammonia, actual or saline, it becomes offensive, but of course I do not mean that this offensiveness is due to the ammonia, but that the careful estimation of the ammonia constitutes a fair and very ready method of determining whether air is in a fit or unfit state to be breathed; I mean that the ammonia is an admirable index. In making these experiments I proceed as follows: I take a large stoppered bottle (a Winchester quart answers the purpose well), wash it and dry it perfectly, and fill it with well washed sand. Take it into the room the air of which you wish to examine and empty out the sand. I have found this the readiest method of filling a bottle with the air I wish to analyse. I now put into the bottle six ounces of distilled water, taking care that it is perfectly free from a trace of ammonia. Shake the water about thoroughly. I now empty it into my test bottle and add my Nessler solution; compare the depth of the tint with my standard solutions. This gives me at once the quantity. In good fresh air this bottle full will only give me the faintest trace of ammonia, but it is most remarkable how immediately we get a notable discoloration when the air becomes in the least degree oppressive. I will not trouble you here with numbers as I shall have occasion to deal before long with these at much greater length, but I would just say if the ammonia (NH_3) is much above one part in a million of air, the effect is at once felt and the atmosphere becomes intolerable. I shut myself in a very small room containing about 350 cubic feet of air for over three hours, carefully stopping up every little hole. I took into the room six bottles full of sand, and emptied out one at the end of every half-hour. The gradual increase of the ammonia in these six samples was exceedingly well marked, as well as in the latter samples a decided increase in the amount of the carbonic acid.

These results I have, moreover, confirmed by the examination of the air of crowded rooms, in which, by the method I have suggested, it can be easily proved, that as the atmosphere becomes oppressive, so the ammonia increases in quantity. Dr. Angus Smith, with no little originality, has clearly proved that the albuminoid ammonia, as estimated by Mr. Wanklyn's method, is also a very delicate test of atmospheric purity. With this I quite agree; I only suggest the estimation of the ammonia when time is an object.

I have examined with great care the amount of ammonia given off by the breath at different times. It is sometimes larger than at others. More, for instance, after taking food, than when fasting; more at night than in the morning. And, moreover, I have noticed this fact, that the ammonia given off by the breath of those persons where the deposit of what is called tartar on the teeth is particularly abundant, is sometimes four, five, or even six times as great as what is usually found in cases where this deposit does not occur in any quantity. And this, I think, explains how the tartar comes to be deposited, viz., by the precipitation of the phosphates. Upon scaling and cleaning the teeth carefully I still found in these cases but very slight diminution in the amount of the ammonia given off. This was originally suggested to me by Dr. Letheby as a matter for investigation.

Hence, I think this, that the careful researches of Dr. Angus Smith and others have conclusively proved the oppressive character of air that has been breathed and rebreathed, is not due to a deficiency of oxygen, or an excess of carbonic acid, so much as it is to the presence of organic matter, and it seems to me that the estimation of the amount of ammonia will be a very fair criterion, indeed, of the purity or impurity of the air we are examining.

But the air is vitiated in other ways. In numerous methods that will occur to you, sulphurous acid becomes a very frequent constituent. Fatal accidents from it, however, are comparatively few, because its presence in small quantities is so easily detected by its powerful smell, and irritating action.

Some years ago, when Dr. Letheby was examining the air of the Underground Railway, it was remarked that the men constantly engaged on that line suffered little or no inconvenience from the sulphurous acid that was present in the air. I have heard it stated, and I believe it to be a fact, that the men on the Metropolitan line applied to the club to which all railway porters subscribe, to have their subscriptions reduced, because of the very few cases of illness occurring amongst those that are engaged on the Underground Railway.

In excess, of course, sulphurous acid is a poison; but it is most remarkable how easily animals become accustomed to breathing it, and a quantity of the gas that is positively poisonous to one, can be respired with perfect impunity by another that has been cautiously, and by degrees, accustomed to it. For example, I placed two mice in a large glass receiver, in which I burnt 0·5 gr. of sulphur. The effect was immediate, and the irritability caused lasted for some time; but by increasing the amount of the sulphur gradually day by day, I can now burn 10·0 grs. of sulphur in the same vessel without anything like the irritating effect on these two mice that 0·5 gr. produced on them in the first instance, and does produce in all cases when exhibited to those unaccustomed to it. So much for use. I do not think that in small quantities when the slight irritability that the sulphurous acid produces in the first instance is overcome, it acts at all injuriously; rather, indeed, I am disposed to think it may be antiseptic in its action, and so positively beneficial. It is to be remarked that I have failed to train plants to bear its action, as I have trained the mice. A very much smaller quantity of sulphurous acid will destroy a plant, than is necessary to kill a very small animal like a sparrow. There is no difficulty in detecting sulphurous acid in air, even when present in such small quantities as one part in 3,000, a blue colour is speedily produced by its action on starch and iodic acid.

The action of *hydrofluoric acid* is a subject of very considerable importance. Indeed, in a recent trial respecting a factory at Bermondsey, upon which I was engaged, and which most of you remember (well-known as the Bermondsey Nuisance Case), it became a matter of great importance to decide whether there was any escape of hydrofluoric acid during the manufacture of what is ordinarily known as "superphosphate." I have made some very careful experiments with this gas. One part of it in about a million and a quarter parts of air will destroy vegetable life. A healthy geranium was completely killed by this atmosphere in about sixteen hours. Animal life is not so sensitive, but still very sensitive to its action. One part in 100,000 parts of air produces marked symptoms on mice exposed to its action. I have not carried the experiments, as yet, so far as to determine the *exact* minimum quantity necessary to kill. One part in 1,000 will kill a mouse in two minutes. At any rate, this is certain, vegetable life is far more sensitive to its action than animal life. The fact that at the time of our visit, Dr. Letheby and myself found that the pear trees in the immediate vicinity of the superphosphate works at Bermondsey, were in full bloom, and that vegetation was generally luxuriant in the immediate neighbourhood, was quite sufficient evidence of the non-escape of hydrofluoric acid. At any rate, our evidence upon that occasion has been quite borne out by the experiments I have recently made, that inasmuch as vegetation had not in the slightest degree suffered, hydrofluoric acid, if present, was not present in sufficient quantity to be injurious to animal life.

The escape of coal gas is another cause, and the last I shall mention to-night of vitiated air. The extent of the estimated leakage of coal gas is something marvellous. This leakage in days when coal is no small price, is a matter that demands attention on the mere ground of economy, besides which, the ill-effects that it will produce when respired for a long time, even though present in the air in the smallest possible quantity, demands attention on the ground of health. Fortunately, its escape when in marked quantity is easily detected by its smell. I can myself detect one part in about 1,200 of air. I find most people can recognise one part in about 800. An atmosphere of 4 per cent. produces a well-marked action on mice. Two mice out of three died in about five minutes in an atmosphere containing 17 per cent., the third one for some reason or another recovered. But even when the gas was in excessively minute quantity, both a mouse, as well as a small geranium, I submitted to its action, became visibly affected after being exposed to its influence for a considerable time; the mouse becoming exceedingly quiet, dull, and heavy, with a complete loss of sprightliness, from which state it took some time to recover, whilst the geranium slowly withered and ultimately died. I will not discuss now to what gas in coal gas (which of course is an admixture) this action is due. It is, perhaps, as yet an open question, but I do feel that inasmuch as coal gas is now so commonly used, it is a matter of great importance that some improved method should be adopted to prevent the leakage of even the smallest quantity, a quantity unrecognised, perhaps, by our smell, and yet which may be a cause, when respired for some hours, of serious detriment to health.

I purpose examining the action of a great many other gases, mixed in various proportions with atmospheric air, upon animal and vegetable life; but as I have ventured to lay these facts before you as a first instalment of experiments, I hope my time will allow me to continue. Permit me to say (although, perhaps, in this opinion you will regard me as somewhat biassed) it seems to me that accurate knowledge on the great sanitary questions of the day, the purity or impurity of the air, as well as of water, must be met, not by any partial or one-sided view of the subjects, either as pure chemists on the one hand, or as pure physicians on the other; but by medicine and chemistry being bound together for enquiries of this kind with a tie stronger than a marriage bond, an iron chain that time can never weaken, and age can never rust. It is this marriage tie that forms the true basis for development.

◆

AMPUTATION IN TRAUMATIC TETANUS (*a*).

By James Edward Kelly, L.R.C.S.I.,

Surgeon to Jervis Street Hospital, and Lecturer on Surgery in the Ledwich School of Medicine.

Mr. James Kelly said he was anxious to propose the question of amputation in traumatic tetanus to the consideration of the Society, and he would base his remarks on a case which had occurred lately in the Jervis-street Hospital. He congratulated the Society that neither his inclinations nor his avocations allowed him to write an elaborate paper, as it (the Society) was spared the wearisome platitudes which too frequently obscured the point of an original communication. He did not mean to be the exponent of this treatment, but to learn the views of the Society and evoke the severest and thorough discussion. He was unprejudiced, but, in the expression of the opinion of the Society, he sought for a guide, a corroboration, or an influential negation, should a case equally suggestive of amputation occur in his subsequent practice.

Case: ——, æt. 28, with compound comminuted fracture of left leg; considerable hæmorrhage checked by carbolic acid, with the additional intention of treating the fracture by Lister's method; no pain, heat, &c., in part, nor any constitutional symptoms until the eleventh day, when fluctuation was detected, and a poultice applied to detach the coagulum, which came away on the thirteenth day, allowing some pus to discharge. On the next morning the tetanic symptoms presented themselves; the wound was enlarged. On the second evening the first spasm occurred. During the spasm the temperature was 104, the pulse 130. Some time after they fell to t. 99·4, p. 95. On the third day an incision was made down to the fracture, and a tri-radiated osseous spiculum, measuring about three-quarters of an inch, was removed from between the two bones where it was firmly impacted. The structures on the anterior and outer portion of the leg were sphacelated; one grain dose of sulpho-cyanide of potassium was given every hour, with a view of destroying the irritability of the muscles, and thus diminishing the waste of tissue, until *curare* could be procured. It lessened the frequency and force of the spasms, relieved the epigastric pain, and enabled the patient to open his mouth. The woorara was administered on the third day, in doses of 1-32 grain. It also diminished the pain and relieved the spasm, its clinical effects varying from those of the sulpho-cyanide of potassium. The pulse and temperature increased towards the termination, the former averaging between 130 and 140. The spasms occurred every ten or fifteen minutes; they were frequently aborted by a few inhalations of chloroform, which notably prevents those induced by voluntary efforts to swallow. The patient described a pain commencing at the seat of fracture, and coursing up along the limb and body, and terminating at the occipital region, after which the spasm would seize him. He died on the fourth morning of the tetanus. The *post-mortem* examination was made about three hours after—of course many of the symptoms and general treatment have been purposely omitted, in this case, as uninteresting.

The *post-mortem* examination disclosed the following—Rigor mortis well developed, most in dorsal aspect of the body, it extended during the autopsy to the anterior muscles; local examination—sphacelated on outer and anterior aspect of limb; the cutaneous branch of the musculo-cutaneous nerve was implicated in the slough, and for some distance stained of a cream or yellow colour. The posterior tibial nerve was also changed, it appeared hypertrophied and congested for about two inches on the proximal side of the fracture. The spiculum, which had been removed, must have been in immediate proximity to the inflamed part. On making the preliminary incision to expose the cord, the congestion of the dorsal structures was remarkable, and the blood had to be constantly sponged away. Even at this early stage the fœtor was perceptible when the spinal canal was opened, the theca was moderately distended with cerebro-spinal fluid, and its surface was not markedly vascular, neither did the cord when exposed appear congested, except at one or two points—one on the posterior surface, near the posterior roots of the sacral nerves; the other on the anterior aspect of the dorsal portion of the cord. This coincidence between the local congestion and the attachments of the efferent nerves coming from the wound, and of the afferent nerves proceeding to the dorsal muscles, may afford a suggestion leading to more

---

(*a*) Read before the Surgical Society of Ireland.

extended investigation. Rokitansky's warning to the inexperienced should be borne in mind, "There is, perhaps, no respect in which moderation in estimating appearances was so much to be impressed on the unpractised observer as in regard to the quantity of blood contained in the pia mater. As a general rule a very moderate injection is erroneously looked upon as congestion." It is a great error to allow our impression to be based on our observation in the dissecting room. Four sections of the cord were taken, and the microscope revealed the following. In all, there appeared congestion of the grey matter.

1st. Through lower part of medulla oblongata; showed nothing additionally abnormal.

2nd. Through cervico-rachidian; enlargement presented an example of granular softening, and a point of extravasated blood near the cervix of the posterior corner of the grey matter.

3rd. Through dorsal part of cord little if any softening; exudation between the cord and pia mater.

4th. Through the lumbar rachidian, enlargement, softening, and exudation. Here also between the pia mater and white substance.

For convenience, Mr. Kelly adopted a familiar and rational subdivision, and examined the pathology on the functional, structural, and zymotic views. The relation to the functional theory which chronologically deserves prior consideration. He said, as in other examples of so-called functional disease, it was principally based on the want of appreciation of histological changes. Until lately the only central change which pathologists observed, and even this most invariably, was vascularity of the cord. That reliable observer, Bentley Todd, recognised no inflammation, no disorganisation, and little vascularity, and ascribed the tetanic symptoms to the increased polarity of the cord, specifying neither cause or effect. Cooper and others regarded as negative the cerebral lesions. The vascularity of the nerves connected with the injury was recognised, and the coincidence of the injury and tetanus, and the occasioned reference of the pain to the injured part—a point by the way denied by Colles ("Surgical Lectures"), constituted the main data for the construction of the functional theory. It is sustained by such cases as related by Langenbeck and others, where the removal of the cause was followed by the recovery of the patient. This view for a long time was most jealously maintained; but more advanced observation has demonstrated the unreliability of the functional hypothesis. Those who were in advance of their contemporaries in recognising structural modification as being essential to the pathology of disease, only recognised increased vascularity of the central, and this even was deprived of any importance by such explanation as that of Colles, who attributed it to interference with the respiration resulting from the laryngeal spasm, &c.

The relation of this congestion to the peripheral stimuli gave a bias to the observers, and it was noticed by Carpenter that the excitability of the cord when once established was sustained by peripheral excito-motor impressions. Franks, Hoffmann, and Meadows, by recording cases of tetanus resulting from direct injury to the spine, give us the first data for doubling the above, as the invariable order. Rokitansky and Demme, by their observations and deductions, arrived at a rational theory of the disease. The former linked the functional view with the structural, by considering that the functional disturbance induced hyperæmia, and this, proliferation of the connective tissue elements, not, however, proceeding to the formation of fibres. The views of Mr. Lockhart Clarke, relative to the condition which he describes as granular softening, are reconcilable with the previously mentioned, and the analogy is further sustained by Mr. Dickinson's observations of the escape of the blood corpuscles, and the lymphous exudation, each of which Mr. Kelly corroborated. Mr. L. Clarke proposed the following questions, some of which have a most important bearing on the treatment of the disease;—

1. Do lesions of the centra persist in these cases which recover (Mr. Clarke believes they do)?

2. Are they the effects of the excitement of the cord resulting from vascular changes?

3. Are they the causes of the spasms (improbable as they exist in other diseases in which no spasms occur)?

4. In what do the spasms depend (*a*), excitability of the cord, hyperæmia, and results (*b*), persistent irritation?

Zymotic Views.—The great mind of Cullen foreshadowed this by a speculation that some other causes besides local injuries were active in the production of tetanus. Larrey and others recognised the epidemic nature of the disease. Flint considers that in tetanus and poisoning from strychnine and its allies, pathology points to blood poisoning. This observation deserves considerable interest from the results of some experiments by Harley, of London, which tend to show that in poisoning from strychnine, brucia, &c., the blood is deficient in its power of absorbing oxygen—a remark which may aid in referring the process of zymosis to defective or excessive oxydation of the blood elements.

Dr. Richardson, of London, at a meeting of the Epidemiological Society, grouped tetanus with the recognised zymotics, and said that he considered that the poison or ferment was produced in the wound. He was struck by the probable good results of inoculation on the lower animals, as a method of elucidating the subject. The converse or transmission from animal to man was observed and recorded by Bitoli as occurring in the Brazils with reference to the question of this being a blood disease; and it would be interesting upon some precise information as to the relation which the separation of the wound bears to the course of the disease. Elliotson has observed cases where the tetanus ran its course to a fatal termination, while the wound healed; and, again, the wound became more unhealthy in character, although the patient improved. Larrey, Rush, and others, opposed this—that tetanus is epidemic in its appearance, is generally conceded, and lately Dublin seemed to have a visitation; within two or three weeks of the period, during which the above case occurred, two others were seen in the Jervis-street Hospital, two in each of two other hospitals, and one in a third, in all, eight cases within a very short period. A similar coincidence has been observed by many, as Colles, Bitoli, and Billroth. Their records bear on the inquiry as to whether we should refer the disease to the miasmatic and enthetic order of zymotic diseases. With regard to the treatment of tetanus Mr. Kelly wished to remind the Society of the sound principle that if a disease seems to yield to various and opposite methods of treatment, Nature does much towards curing the patient, and most probably would do more if she were not impeded by obtrusive science. Few diseases afford such an apt example as tetanus, and it is but too patent that as yet no special treatment can be regarded as reliable. Treatment to be rational must be based on pathology, but, heretofore, the pathology being most unreliable, we must adopt or sustain any line of treatment with caution. On the basis of the functional theory the indications lie principally among medicines which have an inhibitory action on the special properties of the cord, the afferent nerves, muscles, and the efferent. If we consider the cord as an isolated organ apart from its functional manifestations, we can modify its action only through its vascular supply, and the many medicines which paralyze and stimulate the vessels, as opium, belladonna, tobacco, &c., may be regarded with questionable propriety as directly opposing the functions of the cord.

More "anti-functional" may these medicines be regarded, which, like curare, binia, ether, &c., destroy the conductility of the motor nerves. Generally, patients die of exhaustion, and anything which retards this increases the probability of recovery. The action of *curare* has been carefully investigated by Bouvier, Bernard, Spencer Wells, and a host of others, and like other remedies, its supporters cannot claim for it more than a very moderate percentage of success. Ether, owing to its physiological action, may be used with great advantage, as it has the same influence as woorara, without being so dangerous to life; and, also owing to the uncertain character of the woorara, it is not a reliable drug. The sulpho-cyanide of potassium and the extract of the upas suspend the contractibility of the muscles, and, as a preventative of muscular waste, Mr. Kelly has administered the former drug. It is interesting to observe the difference which the atom of sulphur produces between this body and its ally the cyanide of potassium. The active principles of calabar bean (physostigmatin and esserin) have an inhibitory action on the efferent nerves. Perhaps of all the lines of treatment based on the functional theory this is the most rational. Many of the powerful drugs or poisons seem to have a temporary and similar influence on the disease, relaxation of the muscles, and diminution of the spasms. Perhaps the solution of this strange coincidence may be joined in the general depression of vitality, which such so-called remedies produce. On the basis of modification of structure, the treatment directly or indirectly may be reduced to the antiphlogistic, and varies from ice to actual cautery to the spine, from tartarated antimony to stimulation to the extent of intoxication. Zymotic diseases seem as yet to have preserved to a great extent their independence from the incursions of therapeutics. Support and general efforts to eliminate the poison, with perhaps the administration of such drugs, as have antiseptic properties inimical to zymotic action. If of idiomiasmatic class the indication to remove the cause or radiating point by amputation or else, is very obvious. The treatment generally adopted seems to be a reflective or a hap-hazard combination of two or more methods. Of mechanical or surgical treatment the three main lines are directed to the removal of local irritation, as spicules, collections of pús, &c., to the division of afferent nerves, and to amputation of the injured limb. The last includes the other two, and everything claimed for either of them can be advanced with equal truth in favour of the latter. The objections to amputation may be grouped under a few heads. (*a*) Being a zymotic disease, such treatment would be useless. It is not well to deprive the patient of a possibility of recovery on an hypothesis, and even the opponents must countenance the removal of the part which, on Richardson's view, breeds the poison. (*b*) Lesions of the cord prevent recovery. Mr. Clarke regards all classes of recovery as having persistent degeneration, and, before amputation is excluded, we must decide on the amount which renders recovery impossible, neither is there any basis for deciding on the time when amputation is allowable. (*c*) Tetanus sometimes follows amputation, for other diseases we must decide to what extent the tetanus is induced by the operation or malpraxis, as tying nerves, fibrous structures, &c., or to malarial influences. (*d*) There are not sufficient instances of recovery under such severe treatment to justify its adoption. Records are few of the treatment or of its results, but most probably statistics would prove at least that the treatment is not more unsuccessful than many others which are much lauded. In one case of Larrey, the disease was notably mitigated, and another it was stopped for twelve hours, but was reinduced by exposure to cold. In Liston's case the tetanus was cured, but the patient died of exhaustion; and a gentleman, who would address the meeting, had a case in his practice in which a complete recovery resulted. To occupy the attention of the members of the Society was not Mr. Kelly's intention; he was anxious to obtain their views, and he would direct their attention in particular to two heads of inquiry—1st. Is amputation justifiable in any case of tetanus? 2nd. What are the special symptoms which would indicate or contra-indicate this procedure?

STUDENTS' COLUMN.

LECTURES ON HUMAN ANATOMY.

By Walter Rivington, M.S., Lond., F.R.C.S., Eng.,
Surgeon to the London Hospital and Lecturer on Anatomy at the London Hospital Medical College.

Lecture III.

The Sacrum and Coccyx, or the False Vertebræ still remain for our consideration.

The *Sacrum*, or Rump Bone, is composed generally of five, sometimes of six, or only four, vertebræ united, or ankylosed as it is scientifically expressed, and is fitted in between the two expanded Innominate Bones like the key-stone of an arch. It has the shape of a double wedge. It is wedge-shaped from above downwards, with its base at the Last Lumbar Vertebra and its apex at the Coccyx; it is wedge-shaped from before backwards, with its base in front and its apex behind. Moreover, it is curved on itself so as to become concave towards the cavity of the Pelvis and convex in the back. When articulated with the fifth Lumbar Vertebra and the Innominate Bones we see that it has an inclination backwards from the Spinal Column, so that its base forms with the fifth Lumbar Vertebra a prominent angle in front, variously designated Lumbo-Sacral, Sacro-Vertebral, or Vertebro-Sacral Angle or Promontory. It is through the medium of the Sacrum, thus joined on to the Spinal Column and wedged in between the Innominate Bones, that the weight of the trunk is transmitted and flows off on either side through the Ilia to the sockets which lodge the heads of the Thigh Bones, and so to the Lower Limbs and Feet.

The functions of the Sacrum are—1. The transmission of the weight of the Body to the lower limbs; 2. To form the posterior boundary of the cavity of the Pelvis, and afford protection and support to the important organs contained therein; 3. To give attachment to muscles; and 4. To contribute to a firm basis for the trunk in the sitting posture. All these functions being best fulfilled by immobility, the essential feature of the bone is the fusion or ankylosis of its vertebral elements, whilst it is so securely impacted between the Innominate Bones and fixed by strong ligaments, that it cannot be displaced except by an extreme of violence, which would contund and smash the neighbouring structures, and speedily lead to a fatal issue. All the minor details of the bone have reference to the performance of one or other of the uses assigned to it. It is smooth anteriorly, for the lower end of the alimentary canal lies on it, the Pyriformis Muscle only intervening. It is curved, and its apex is turned forwards that it may not project inconveniently, but afford a rounded contour for sitting or lying, and for the same reason the processes of the bone are reduced in size. Even as it is, the posterior aspect of the Sacrum comes very near to the surface of body, and persons long confined to bed are thus rendered peculiarly liable to the formation of troublesome ulcers in this region, called bed-sores. I take no account at present of the special adaptations of the female Sacrum for childbearing, as this will come in more properly at a later period.

Regarded as a whole the Sacrum, being triangular in shape, possesses two surfaces, two borders, and two extremities, or an Apex and a Base.

The *Anterior Surface*, much wider above than below, is concave and shows plainly the composition of the bone by the union of its constituent Vertebræ. It presents in the centre the anterior aspects of the Bodies of the Five Sacral Vertebræ, diminishing in size from above downwards, and separated by four Ridges corresponding to their points of junction. Each ridge leads on either side to a large Foramen or Hole called the Anterior Sacral Foramen, at which it terminates. From the Foramen passes outwards a Groove, wide and shallow. There are four Foramina and four Grooves on each side, and between them are placed prominent ridges. The Foramina, which, like the Bodies, diminish in size from above downwards, give exit from the Sacral Canal to the Anterior Branches of the Sacral Nerves, and permit blood-vessels to pass both inwards and outwards; the Grooves lodge the Nerves after leaving the Foramina. Observe that these Foramina are placed at the points of junction of the Vertebræ, showing plainly that they are formed by the coalescence of the adjacent Notches, and that the ridges between the notches represent Pedicles. Externally to the Sacral Foramina is a continuous surface of bone, wider above than below, diversified only by the Grooves, called the Lateral Mass, of the Sacrum, and corresponding to the fused Anterior Transverse Processes or Ribs of the Sacrum.

The First Vertebra is deeper in front than behind like the Last Lumbar, which it much resembles. The other Vertebræ are deeper behind than in front, in consequence of the curve backwards, and flattened antero-posteriorly. Each Foramen is bounded to a greater extent by the upper than the lower of the two Vertebræ contributing to its formation; in other words, the Inferior Notches are larger than the Superior.

The *Posterior Surface* is convex, very irregular, and rather smaller than the anterior. It presents the following objects:

In the centre is a row of projecting *Spinous Processes*. That belonging to the first Sacral Vertebra is usually distinct from the others; the Second, Third, and part of the Fourth may, and often do, coalesce into a vertical tubercular crest; the remainder of the Fourth and the Fifth are altogether deficient. Proceeding on either side outwards from the Spinous Processes we come to the *Laminæ*, which are large, strong, sloping downwards, and often distinct in the First Vertebra; without special features in the Second, Third, and Fourth, and deficient in the Fifth Vertebra. Owing to this deficiency, the Sacral Canal is completely exposed below, uncovered by bone, and appearing as a wide groove, bounded on the outside by a tubercular ridge formed by the coalescence of the two lowest of the Articular Processes. These processes run vertically from above downwards, immediately beyond the Laminæ. As usual the first are distinct and prominent, the second and third are insignificant; the fourth and fifth are united into the ridge just mentioned, which is prolonged downwnards and projects beyond the Apex of the Sacrum. The eminence thus formed is called the Sacral Horn or Cornu, and joins a similar prominence on the Coccyx.

Immediately on the outer side of the Articular Processes is a row of four Foramina, the Posterior Sacral Foramina. These are smaller in size than the Anterior, but exactly opposite to them, and give exit to the posterior branches of the first four Sacral Nerves. The fifth Sacral lies in a notch completed by the Coccyx into a foramen, and placed beneath the Sacral Horn. Beyond the Foramina is another row of Processes, which represent the posterior true Transverse Processes. The upper pair are well-marked; the rest mere tubercles. These tubercles attach the Sacro-Iliac and Sacro-Ischiatic Ligaments.

Between the Spinous Processes and the Transverse, the surface of the Sacrum is depressed, forming a groove called the Vertebral Groove of the Sacrum, for the origin of a large muscle by which it is filled.

The *Lateral Aspects* or *Borders* of the Sacrum are surfaces above but mere edges below. The surfaces above are divisible into two parts, an anterior and a posterior. The anterior part being ear-shaped is called the Auricular Surface; it articulates by fibro-cartilage with a corresponding surface on the Ilium. The posterior part is rough and irregular, exhibiting depressions for the more secure attachment of the strong Sacro-Iliac Ligaments.

The edges below the Auricular Surfaces are uneven, give attachment to the Sacro-Sciatic ligaments, and present at the lowest part a deep notch, which is converted into a foramen for the anterior branch of the fifth Sacral Nerve either by ligament or by the Transverse Process of the first vertebra of the Coccyx.

The *Base* of the Sacrum presents the parts seen in a view of the upper surface of a Vertebra. The Body in front is widest transversely, of an oval shape, and corresponds to the lower surface of the last Lumbar Vertebra, which is joined to it by the thick Inter-vertebral Disc of fibro-cartilage. Behind is the section of the Spinal Canal, triangular in shape, and bounded by the Body in front and the Pedicles and Laminæ at the sides and behind. Projecting from the junction of the Laminæ is the Spinous Process of the first Sacral Vertebra, usually distinct. Flanking the aperture of the Sacral Canal are the Superior Articular Processes, which bear oval surfaces, concave from side to side, plane from before backwards, and directed backwards and inwards for articulation with the Inferior Articular Process of the last Lumbar Vertebra. The Pedicles present on their upper edges a Notch which is bounded by the Body and the Articular Process, and corresponds to the inferior Notch of the fifth Lumbar Vertebra, forming with it an Inter-vertebral Foramen.

Outside the Body of the first Sacral Vertebra, on each side, may be seen a smooth triangular surface, which is continuous with the Iliac Fossa when the Sacrum and Ilium are united. This surface is limited in front by a rounded margin, formed by its junction at an angle with the anterior surface, and constituting part of the brim af the True Pelvis. These lateral surfaces are named the Alæ or Wings of the Sacrum.

The *Apex*, directed downwards and forwards, is a small oval concave surface, articulating with the upper surface of the Coccyx.

The only remaining object is the *Sacral Canal*. At its commencement triangular, it gradually becomes flattened from before backwards, following the Sacral curve, and lodging the terminal nerves of the Cauda Equina.

The Sacral Nerves divide within the Canal into anterior and posterior branches, which pass out respectively through the Anterior and Posterior Sacral Foramina. At the lower part the Sacral Canal is unroofed through the deficiency of the Laminæ, but the Canal is rendered complete by fibrous tissue stretching across between the Cornua.

The Anatomy of the Sacrum may be thus exhibited in a tabular form:—

The Sacrum, formed of 5 ankylosed vertebræ, possesses	2 Surfaces, anterior and posterior; 2 Lateral Borders; An Apex and a Base; A curved, flattened continuation of the Spinal Canal.
Anterior Surface. Concave.	5 Bodies separated by 4 Ridges, ending at
On each side	4 Holes, leading to
On each side	4 Grooves for the Anterior Sacral Nerves.
Outside Grooves, on each side	5 Fused Transverse Processes.
Between Holes and Grooves	Ridges or Pedicles for Pyriform Muscle.
Posterior Surface. Convex.	
In centre	3½ Spinous Processes flanked by
On each side	3½ Laminæ, outside of which are
On each side	5 Articular Processes, the last pair being The Cornua of the Sacrum.
Outside Articular Processes, on each side	4 Holes. The Posterior Sacral Holes for Posterior Sacral Nerves.
Beyond Holes, on each side	5 Transverse Processes.
Between the Spines and Transverse Processes is	The Sacral or Vertebral Groove.
Below in centre is	The Unroofed Sacral Canal.
Lateral Borders.	
Each presents above	An *Auricular* Surface in front; A *Ligamentous* behind.
Each presents below	A Narrow Edge, And a deep Notch for fifth Sacral Nerve.
Base.	All the parts seen on a view of an upper surface of a Vertebra; Body, Arch, Pedicles, Laminæ, Spinous Process, Notches, Articular Processes, also Alæ of Sacrum.
Apex.	Smooth Concave Surface for Coccyx.

To see the structure of the Sacrum an antero-posterior vertical section should be made. The Bodies are then shown to be composed in the interior of spongy tissue surrounded by a thin layer of compact tissue. Between the first two Vertebræ always, and between the others sometimes, may be observed a space filled with soft Intervertebral Substance, the bones being only united circumferentially. In some specimens the anterior surface of the Sacrum exhibits a wide interval between the First and Second Sacral Vertebræ, and these Vertebræ appear to be joined at an angle which may be mistaken for the Sacro-Vertebral Angle. It is interesting to observe that in Man the Sacrum joins the Ossa Innominata by means of the anterior transverse processes or Ribs belonging to its three upper segments. In some of the Mammalia only one Sacral Vertebra joins the Ilium, and in the others, as in the adult Chimpanzee, there are only two. The larger number of elements entering into the Pelvic Arch in Man has evident reference to the increased strength of articulation required for his adaptation to the erect posture. Other features of the Sacrum peculiar to Man are its great proportional breadth, its double concavity on its anterior aspect, the suppression of its Spines, and the large size of the Sacral Foramina.

The Sacrum varies considerably in different Skeletons. If its first Vertebra does not join the others, but remains separate and forms part of the Lumbar Curve, the Sacrum is reduced to four Vertebræ; and, without actual separation, the first Vertebra may slope backwards from the second, and have its Spinous Process, Laminæ, Transverse and Articular Processes, distinct.

On the other hand the process of fusion may have gone so far as to involve the last Lumbar Vertebra.

The Spinous Processes vary much. They may be altogether wanting, with or without deficiency in the Laminæ, or the First Spinous Process may be wanting, accompanied by want of union of the Laminæ.

The affection known as Spina Bifida, which is the result of deficiency of the Laminæ and Spines of the Vertebræ is most common at this spot. In some specimens the Laminæ of the first Vertebra are united, but each developes a separate spine. In others the Sacral Canal is open to too great an extent below, or even in its whole extent, like a narrow gutter (*a*).

The curve of the Sacrum is stated by Mr. Quain (*b*) to present three chief varieties. In one set of bones the anterior surface was nearly straight. with a slight curve at the upper end; in a second the curve was nearly uniform and considerable in the whole length; in a third set the curve chiefly affected the lower end, the upper end being straight. The curve gives us little assistance in determining the sex. Indeed, as stated by Mr. Harrison in his excellent manual, the *Dublin Dissector*,—"The sexual characters are uncertain and very differently stated by different writers" (*c*). Those most relied on are the greater width and smoothness of the female sacrum, and its curvature being less in degree, and chiefly confined to the lower end. Its greater inclination backwards can only be observed when it is articulated, and then the features of the other bones of the Pelvis would serve to determine the sex. The conclusion is that "we cannot always determine to which sex a detached Sacrum belongs."

The *Coccyx* need not detain us long. It is a degenerate appendage, noted chiefly for negative characters; the possible basis of an undeveloped tail, a link which binds us to the brute creation. Consisting of four, sometimes five, ankylosed Vertebræ (*d*), and triangular in shape, it presents two Surfaces, two Borders, an Apex and a Base. Of the Surfaces the Anterior is slightly concave in continuation of the Sacral Curve, and indicates by three grooves the composite nature of the bone, while the Posterior is convex and exhibits, in addition to transverse grooves between the bodies, vertical rows of tubercles, representing the Articular Processes. The upper pair of Articular Processes being prolonged to meet the Cornua of the Sacrum, are called the Cornua of the Coccyx. Both the Anterior and Posterior Surfaces are covered by the Sacro-Coccygeal Ligaments.

The Borders present little eminences, representing Transverse Processes, separated by Notches, indicative of the points of junction of the Vertebræ. The First Coccygeal Vertebral has long Transverse Processes, which may curve upwards to meet the lateral part of the Sacrum as already described. The Borders attach the Sacro-Sciatic Ligaments and Coccygeal Muscles.

The Base is an oval surface joined by fibro-cartilage to the Apex of the Sacrum. The Apex is either Tubercular or Bifid, and attaches the Sphincter Ani Externus and Levatores Ani.

The anatomy of the bone and the gradual degeneration of the Vertebræ may be thus exhibited:—

Bodies—Present in all.

Arch and *Hole*—None. *Pedicles*—None. *Laminæ*—None.

Notches—Only in the first Vertebra. *Foramina.*—None.

Transverse Processes—Rudimentary in the first three.

Articular Processes—Rudimentary in the first three, the upper pair being developed into projections called the Coccygeal Cornua.

Spinous Processes—None.

In applying the terms "degeneration" and "degradation" to the Sacrum and Coccyx I by no means intend to give in my adhesion to any particular theory of organisation, but simply to express the fact of the gradual obliteration of the characteristic features of the Vertebræ, at the lower end of the Column. This alteration corresponds entirely to the conditions of human existence; and equally in accordance with *their* requirements is the elevation and development of the Coccygeal Vertebræ in other animals—whether in forming an organ of locomotion or support, or in acting as a prehensile instrument comparable to the Human Hand. There is no part of the body which presents more interesting and instructive modifications than the Coccyx.

In number the Coccygeal Vertebræ may range from 2 in certain Bats to 270 in some of the Sharks. Among the Mammalia the Long-tailed Pangolin has 46. Some Oppossums with prehensile tails have 46, some Baboons 31, some Spider Monkeys 33, and the Kangaroo 21 to 25. In some animals, moreover, the Coccygeal Vertebræ are as perfect and moveable as in the other regions, or even superior in both respects. It requires, therefore, a survey of the Vertebrate Sub-kingdom to do adequate justice to the merits of the Coccyx.

"The division of the Vertebræ," says Mr. Mivart, "into *true* and *false* is seen to be a very arbitrary one when we extend our view, as all are 'true' in Serpents, and those which are 'false' in Man are 'true' even in some members of his own class, *e. g.*, the Cetaceans. On the other hand, many Vertebræ which are reckoned to be 'true' in him are 'false' in other animals. Thus in Birds the process of anchylosis invades the lumbar and dorsal Vertebræ. In Tortoises all the trunk Vertebræ are fused, and therefore 'false;' while in the Glyptodon none of the Vertebræ except the Coccygeal can be said to be 'true' ones. Again, Vertebræ may be more thoroughly false than even in Man, as in the Sacrum of the Rhea (or American Ostrich), where between the hip-bones they abort and are represented only by a long narrow strip of bone. Degradation is a constant character of the last Vertebræ in all classes of Vertebrates" (*a*).

A brief notice of the nomenclature of the False Vertebræ may not inappropriately terminate this lecture. The term Coccyx is derived from the Greek word κοκκυξ, a cuckoo, an appellation assigned to that unnatural bird on account of the amorous and familiar cry (*b*) which not ungratefully salutes our ears in the spring. The Coccyx, however, is so named, not on account of any emitted note, although according to Dr. Ramsbotham "it is called vernacularly the Huckle or Knuckle and even the Whistle Bone," but from a fancied resemblance to a Cuckoo's beak, which is more or less arched and slightly cleft (*c*). In our common variety of Cuckoo the beak or bill is black, strong, and curved. The English Cuckoo is the more interesting to us because its habits were investigated by Dr. Jenner and recorded by him in a paper in the "Philosophical Transactions." Observing these habits the Romans applied the word Cuculus, Cuckoo, first as a term of reproach, and then to the adulterous husband because he acted like the Cuckoo, who drops his eggs in another birds nest, whilst the victimised husband was called Cucurra or Hedge Sparrow, the bird whose nest was often selected by the Cuckoo for the residence of its young, and who in happy ignorance educated the supposititious brood.

With the Grecian Gods, adultery was no uncommon recreation, and Jupiter is said to have transformed himself into a Cuckoo in order to secure the affection of Juno. Our English word Cuckold, means one who has been served as the Cuckoo serves other birds, and to judge from the frequency with which the allusion occurs in Shakespeare, Jonson, and many other writers, especially the dramatists, it would appear that the state of morals in our country was not very exemplary in the 17th and 18th centuries.

Looking at the secondary meaning of the terms Cuculus and to the anatomical relations of the Tail-bone, I am inclined to think that the application of the name Coccyx had as much to do with Cuckoldom, as to a supposed resemblance of the Coccyx to the beak of the bird in question. At all events, it is singular that married men, whose wives have been unfaithful, should have been popularly invested with Horns, and that the term Horns has been applied to the processes projecting upwards from the Coccyx. Of this point I have met with no explanation at present, indeed the origin of Horns, as the badge of Cuckoldom, has been learnedly discussed in many works without definite result.

(*c*) *Dublin Dissector*, Vol. II., p. 71.

(*d*) Professor Humphry gives five as the normal number of the Coccygeal Vertebræ. *Op. cit.*, p. 456.

(*a*) Lessons on Elementary Anatomy, p. 39.

(*b*) The Cuckoo is silent some time after his arrival. By some the female is said to be mute, while others assert that the note is alike in both sexes, and it has been remarked that early in the season the note begins with a minor third, ascends to a major third, next to a fourth, then to a fifth, after which his voice breaks and he does not attain to a minor sixth. The note of the Cuckoo is a call to love, and he sits on the bare bough of a tree repeating his song, which he loses when the amorous season is over. This note is so uniform that the name seems to have been derived from it; and thus we have in the English Cuckoo, in the French Cou-cou, in the Italian Cuculo, in the German Kuckuk, the Latin Cuculus, and the Greek Κοκκοξ.—"Encyclopædia Metropolitana." Article, "Cuckoo." [I am indebted to this source for much of the information in the text.]

(*c*) Generic Character of Cuculus.—Beak more or less arched and slightly cleft. Nostrils surrounded by a naked skin, tail cuneiform, consisting of ten feathers and in some species twelve; toes, two before and behind.

In turning to the Sacrum, we reach a higher and a purer atmosphere, but no great certainty as to the true meaning of the term. Dr. Ramsbotham, in a learned appendix to his work on "Obstetric Medicine and Surgery," has discussed the subject at length, and gives the various explanations which have been offered. They may be thus epitomised :—

1. Because the Sacrum or the parts around were offered up in Sacrifice. For this there is no authority, and the ancients either sacrificed the whole animal or the entrails alone.

2. Because it is the largest bone in the Spine. Rufus Ephesius, a great Greek authority on Anatomical names, says, "We call it the Sacred bone after the Ancients, who called large things Sacred."

3. Because it supported the lower bowel and organs of generation which were held Sacred.

4. Because it was supposed to perform some Sacred and mystical office in labour, opening by Divine power, and shutting again.

5. Because it supported the *Secret* parts, the term Sacer meaning Secret as well as Sacred.

6. Dr. Ramsbotham would trace the Greek term ἱερον Sacred, applied to the Bone before the time of Hippocrates, to a Hebrew root Heron or Herun, signifying conception and gestation, transferred to the Greek language. He thinks that the Greeks derived the name of Juno Ἡρη from the same root, Juno Lucina being the president of parturition. In this connection the ἱερον ὀστεον, or Sacrum, would mean the bone connected with the "organs of generation, and chiefly affected by the throes of parturition."

Butler, in his "Hudibras," assigns the origin of the word to a superstition of the Jews, which arose after the Christian Era. Although hackneyed, the passage may be quoted again. It was regularly quoted by my predecessor and teacher, Mr. John Adams, the best lecturer on Anatomy of his day.

> "The learned Rabbins of the Jews,
> Write there's a bone which they call Luz;
> I'th rump of man of such a virtue,
> No force in Nature can do hurt to.
> And therefore at the last great day,
> All th' other members shall they say
> Spring out of this, as from a seed
> All sorts of Vegetals proceed;
> From whence the learned sons of art,
> Os Sacrum justly call the part. Canto ii. Part iii.

A similar superstition existed among the Mahommedans, who held the lower part of the Spine Sacred, and Mahommed taught that a man's body is entirely consumed in the Earth with the exception of the Os Coccygis, which would remain uncorrupted till the last day, as a seed from whence the whole could be renewed.

It is quite possible that none of the explanations offered may be correct. None of them take account of the importance of the bone in an architectural point of view, the keystone of the Pelvic arch, the pedestal, or "Basilar Bone" by which the whole Vertebal Column and the upper part of the Body are upheld.

BECHAMP, M. A.—"On the Spontaneous Alcoholic and Acetous Fermentation of the Liver, and on the Physiological Alcohol of Human Urine." *Acad. des Sci.*, Dec. 30, 1872.

HISTOLOGY.

FORT, J. A. — "Traité Elémentaire d'Histologie." Deuxième Ed. ; Paris, 1873.

ORGANS OF LOCOMOTION.

HEITZMANN, O.—"Observations on Bone and Cartilage." *Vienna Med. Jahrb.*, Vol. 4, 1872. Dr. Heitzmann considers, firstly, the cellular elements of normal bone; secondly, the changes of bone in inflammation ; thirdly, the formation of blood in inflamed bone ; fourthly, the structure of hyaline cartilage ; fifthly, the formation of blood and bone from cartilage ; and, lastly, he makes some valuable observations on inflamed cartilage. For a very careful summary of his researches the reader is referred to Dr. Klein's article in *Med. Record*, Jan. 29 and Feb. 5.

OLLIER, M.—"Experimental Researches on the Mode of Growth of Bone." *Arch. de Physiol.*, Jan.

DURAND, J. P.—"On the Normal Torsion of the Humerus in Vertebrata." *Acad. des Sci.*, Dec. 23, 1872.

BESWICK-PERRIN, J.—"Record of Irregular Muscles noticed in the Dissecting-Room at King's College, London, during the session 1868-69, 1869-70, 1870-71." *Med. Times and Gaz.*, Jan. 11, &c.

BLOOD.

MATTHIEW AND URBAIN.—"On the Gases of the Blood." Physiological experiments on the circumstances under which their proportions vary in the arterial system. *Arch. de Physiol.*, No. 9, 1872.

CIRCULATION.

STRICKER.—The *Med. Times and Gaz.*, Jan. 11, quotes the results obtained by Stricker and communicated by him at the meeting of the Gesellschaft der Aerzte, Vienna, Dec. 13, 1872, relative to the temperature of the heart and lungs. He finds that the blood is cooled by the lungs; that there is a difference between the temperature of the wall of the left ventricle and that of the contained blood; that the chief source of the generation of heat is in the muscles of the cardiac ventricles ; and, lastly, that temperature is highest in the walls of the left ventricle, then in those of the right ventricle, then in the blood of the right ventricle, and then in the blood of the left ventricle. The last fact is explained by the blood of the right ventricle not being passed through the lungs.

BRADLEY, S. M.—"Tricælian Human Heart." The heart consisted of two auricles and one ventricle, from which a single artery arose, giving off first of all two pulmonary arteries, and then pursuing the ordinary course of the aorta. There was no trace of a ventricular septum. The case was one of arrested cardiac development about the ninth week of intra-uterine growth. *Brit. Med. Journ.*, Jan. 11.

LANDOIS, L.—"The Doctrine of the Arterial Pulse. ("Die Lehre von Arterienpuls.") Berlin.

HEUBNER—"Researches on the Special Distribution of Intra-Cranial Arteries." *Centralblatt*, Dec. 7, 1872. This paper is the subject of a leading article in the *Brit. Med. Journ.*, Jan. 25th, in which Heubner's conclusions are very carefully detailed.

RESPIRATION.

ONIMUS.—"Action of the External and Internal Intercostals." *Soc. de Biol.*, Jan. 11.

NUTRITION.

VOIT.—"On the Nutritive Value of Gelatin." *Zeitschrift für Biologie*, Vol. 8. Voit's experiments go to prove that gelatin lessens the consumption of albumen in the organism, and hence that less albuminous food is needful when given with gelatin; the power of gelatin in this respect exceeds that of fats and carbo-hydrates. Dr. Brunton has given a most comprehensive *résumé* of Voit's views in the *Medical Record*, Jan. 22.

Voit, Carl.—"The Importance of Lime in Nutrition." *Zeitschrift für Biologie*, Vol. 8, Part 3, 1872.

Brucke, E.—"On the Mode in which the Carbo-Hydrates are Digested and Absorbed." *Wiener Sitzungsberichte der Mathem. Naturw. Cl.*, Vol. 56, Part 3. Brücke's views are detailed by Dr. Ferrier in the *Med. Record*, Jan. 22.

INNERVATION.

Fournier, E.—"Experimental Researches on the Function of the Brain." Paris.

Ranvier, M. L.—"On the Degeneration of Nerves after Section of them." *Acad. des Sci.*, Dec. 30, 1872.

Arloing and Tripier.—"Contribution to the Physiology of the Vagus Nerve." *Arch. de Physiol.*, No. 9, 1872.

Schiff, M.—"The Vagus Nerve as an Accelerator of the Movements of the Heart." *Lo Sperimentale*, Nov., 1872.

Prevost, M. J. L.—"On the Distribution of the Chorda Tympani." *Acad. des Sci.*, Dec. 30, 1872.

Vulpian.—"Consequences of Section of the Chorda Tympani." *Soc. de Biol.*, Jan. 11.

Schlesinger.—"On Reflex Movements of the Uterus." Dr. Schlesinger's experiments would seem to prove that uterine movements may be induced by reflex excitation of the centre. *Stricker's Med. Jahrb.*, 1873, Vol. 1.

REPRODUCTION.

Neumann, E.—"The Development of the Spermatozoa." *Centralblatt für die Med. Wissenschaften*, Dec. 28, 1872.

MEDICINE.

MORBID STATES OF THE BLOOD.

Mosler, F.—"Die Pathologie und Therapie der Leukämie." Berlin. ("The Pathology and Therapeutics of Leukæmia.")

GENERAL DISEASES.

Schueppel, O.—"On the Origin and Structure of Tubercle." Dr. Schueppel's views are very fully discussed by Dr. Cayley in the *Med. Record*, Jan. 22 and 29, and his views as to the identity of tuberculosis in man with the cattle-disease known in Germany as the "pearl-sickness" are fully recorded in a leading article in the *Med. Times and Gaz.*, Jan. 11.

Parrol.—"Inoculation of Tuberculous products." *Soc. de Biol.*, Jan. 11.

Adams, Robert.—The second edition of Dr. Adams' well-known work "On Rheumatic Gout or Chronic Rheumatic Arthritis of all the Joints" has just been issued.

Dujardin-Beaumetz.—"On Propylamine in the Treatment of Acute Articular Rheumatism." *L'Union Med.*, Jan. 16 and 18. The statements of this author and others who have used the propylamine lead us to think that in it we have a most useful agent in the treatment of rheumatism.

Mussy, N. G. de.—"Clinical Lessons on the Treatment of Rheumatism." *L'Union Med.*, Jan. 9, 14, and 28.

Peacock, Thomas P.—"On the Blister Treatment of Rheumatism." *Brit. Med. Journ.*, Jan. 18. Dr. Peacock regards this treatment as essentially curative, operating apparently as an outlet to the *materies morbi*, as well as alleviative.

Picot, Constant.—"On Acute Rheumatism and its Diverse Manifestations among Children." (Du Rheumatisme Aigu et de ses Diverses Manifestations chez les Enfants.") Paris.

FEVERS.

Blatin.—"On Small-Pox." *Bull. Gen. de Ther.*, Dec., 1872.

Russell.—"On the Modifying Influence of Vaccination." *Glasgow Med. Journ.*, Nov., 1872.

Silbergleit.—"On the Employment of Liquor Ferri Sesquichloride in Small-Pox." *Berl. Klin. Wochen.*, Dec. 9, 1872. He has used it with advantage in cases where the throat affection was one of the worst symptoms. He gives twenty to thirty drops of it with glycerine every hour.

Zuelzer, W.—"On the Pathology and Therapeutics of Variola." *Berl. Klin. Wochen.*, No. 51, 1872. Dr. Zuelzer records some most interesting cases of severe hæmorrhagic small-pox, which he considers as quite distinct from those cases in which the hæmorrhage follows the usual eruption. He thinks that in the pustular small-pox dessication can be hastened, the skin protected, and risk to life and appearance diminished by members of the benzol series, of which he prefers xylol. We must refer the reader to Dr. Woodman's very careful account of Dr. Zuelzer's investigations in the *Med. Record*, Jan. 29.

"Causation of Enteric Fever." Leading article *Med. Times and Gaz.*, Jan. 25.

Lubanski, M.—"Pernicious Attack in the Course of Typhoid Fever." *Lyon Med.*, Jan 5.

Bouchardat.—"On the Etiology of Typhus Fever." *Acad. de Med.*, Jan. 6. He confutes Chauffard's view, who regarded it as a matter of race. M. Bouchardat, on the other hand, contends that its chief factors are famine and overcrowding.

Colin, M. L.—"On the Migration of the Blood-Pigment through the Vascular Walls in the Venosity of Marsh-Fever." *Acad. des Sci.*, Dec. 30, 1872.

DISEASES OF THE ORGANS OF CIRCULATION.

Chapman, S. H.—"Researches on Pericarditis." *Amer. Journ. of the Med. Sci.*, Oct., 1872. Dr. Chapman's researches are confirmatory of Stricker's view that in inflammation all living cells can change by division into pus cells.

Daldy, Thomas Mee.—"On Disease of the Right Side of the Heart." Dr. Mee Daldy urges the importance of a more careful consideration of disease of the right side of the heart during life. *Brit. Med. Journ.*, Jan. 25.

Fayrer, J.—"On Fibrinous Concretions in the Right Side of the Heart as a Cause of Death after Surgical Operations." *Med. Times and Gaz.*, Jan. 18. This is an extremely interesting and suggestive paper.

Peacock, T.—"Disease of Aortic and Mitral Valves with Embolism of Right Middle Cerebral Artery." *Path. Soc. Lond.*, Jan. 18.

Freidreich, A.—"Traité des Maladies du Cœur." Paris. ("Treatise on Diseases of the Heart.")

Huret, A.—"Tribut à l'Histoire de l'Embolie des Artères Vertébrales." Paris. ("Contribution to the History of Embolism of the Vertebral Arteries.")

Tomkins, A. Wellesley.—"Case of Hæmorrhage into the Peritoneal Cavity." *Brit. Med. Journ.*, Jan. 11.

DISEASES OF THE ORGANS OF RESPIRATION.

Franck.—"Encysted Effusion of the Pleura simulating in its Course and Symptoms a Cavity of the Lung." *Bordeaux Med.*, Jan. 5.

Lilly, J. H.—"Empyema Treated Successfully by Pneumatic Aspiration." *Glasgow Med. Journ.*, Nov., 1872. Over eight gallons of fluid were removed.

Thaon.—"Bayle's Granulation and Chronic Granular Phthisis." *Soc. de Biol.*, Jan. 11.

DISEASES OF THE LIVER.

Peacock, T.—"Obstruction of Portal Vein with Atrophy of the Liver." *Path. Soc. Lond.*, Jan. 7. The thrombus in this case was apparently partly an outgrowth.

DISEASES OF THE KIDNEYS.

Garrod, A. B.—"On Renal Calculus, Gravel and Gouty Deposits, and the Value of Lithium Salts in Their Treatment." *Med. Times and Gaz.*, Jan. 25 and Feb. Dr. Garrod contends that as agents to prevent the deposition of uric acid or its salts in the cavities or tissues of the body the lithium salts are of great value.

Johnson, George.—Dr. Johnson is communicating to the *Brit. Med. Journ.* a series of lectures "On the Pathology Diagnosis and Treatment of Bright's Disease." The first lecture (Jan. 4 and 11) is devoted to the minute anatomy and physiology of the kidney, the physical characters of the urine, the mechanism of albuminuria, the mode of testing for albumen, the history and definition of the term "Bright's Disease," proofs of its constitutional origin and the changes which occur in the gland cells of the kidney. He shows how changes in the basement membrane of tubes and Malpighian corpuscles are often misinterpreted; he alludes to the fact that during the progress of the disease, changes in the blood-vessels in the kidneys and other organs occur later and less constantly than in those which affect the secreting tissue of the gland; he draws attention to the great diagnostic value of morbid products appearing as tube casts in the urine; and, finally, he indicates the mode of examining urinary sediments. The second lecture (Jan. 25 and Feb. 1), is devoted to the consideration of the general symptoms of acute Bright's disease, the microscopic appearances of the urine, the morbid anatomy of the kidney, the physiology of the morbid process, the varieties of acute Bright's disease, the changes in the blood, the etiology, diagnosis, and prognosis.

Dr. Johnson, in reply to Dr. L. Beale, also writes a brief paper in the *Brit. Med. Journ.*, Jan. 18. He suggests a mode of demonstrating arteries with increased thickness of true muscular tissue in their walls. "Let a section of one injected healthy kidney be compared with one from an injected small granular kidney. The size of the canals of the afferent Malpighian arteries and the normal thickness of their walls are both well known and remarkably uniform. A comparison of these particular arteries from the two kidneys will show that, while the canals may be of equal size in the two specimens, the muscular walls are more than twice the normal thickness in the diseased kidney.

Ollivier, A.—"On Hæmato-Fibrinous Pyelo-Nephritis." *Archiv. de Physiol. Norm. et Pathol.*, Jan. The case recorded is worthy of study. The patient, æt. 72, had persistent hæmaturia for six years for which no cause could be assigned. He died of bronchitis. The autopsy revealed the following appearances in the right kidney:—On section it was found to be converted into a series of variously sized pouches filled with fibrinous coagula; when these clots were removed the kidney appeared to consist merely of a cavity divided into cells by septa, corresponding to the divisions between the original lobes. The supposition is that the hæmorrhage was due to rupture of the aneurismal arteries, and that by the coagulation of part of the blood in the pelvis of the kidney the calyces first were distended and then the entire kidney, the secreting tissue becoming atrophied by compression.

DISEASES OF THE NERVOUS SYSTEM.

Bourneville.—"Clinical and Thermometrical Studies on Diseases of the Nervous System." Paris.

Anstie, F. E.—In a short paper in the *Brit. Med. Journ.*, Jan. 18, Dr. Anstie briefly recapitulates his views as to the pathology of "Sick-Headache" as follows:—"Migraine is almost the only neuralgia of the period of bodily development, and depends on inherited defects in the nutrition of the medulla oblongata, and is intimately mixed up with, and frequently interchangeable with, other and more formidable nervous diseases, which are also the results of similar defects in the nutrition of the medulla; and it is, so to speak, a matter of chance whether a person born of a certain race will have migraine, epilepsy, or asthma."

Clarke, Lockhart.—At the *Clin. Soc. Lond.*, Jan. 10, Dr. Clarke brought forward an interesting case of cysts in the cerebellum.

Jeffroy.—"Note on the Differential Diagnosis between Labio-Glosso-Laryngeal Paralysis of Bulbous Origin and of Cerebral Origin." *Soc. de Biol.*, Jan. 11.

Gombault.—"Note on a Case of Spinal Paralysis of the Adult." *Archiv Gen. de Physiol.*, Jan.

Vulpian.—"On Lesions of the Spinal Cord in Muscular Atrophy and Paralysis consequent on Small-Pox." *Archiv. de Physiol.*, Jan.

Westphal.—"Affections of the Spinal Cord in Paraplegia consequent on Small-Pox." *Berl. Klin. Wochen.*, No. 47, 1872.

Charcot.—"Some Anomalies of Locomotor Ataxy." *Mouv. Med.*, Nos. 12 to 18, and 20, 22, and 24, 1872, Jan. 4, 1873.

Thompson, Henry.—"Clinical Lecture on a Fatal Case of Chorea." *Med. Times and Gaz.*, Jan. 18.

DISEASES OF THE SKIN.

Hutchinson, Jonathan.—"Selected Extracts from Clinical Lectures on Disease of the Skin." *Med.. Times and Gaz.*, Jan. 18.

Bassereau, E.—"Eczema Rubrum: Importance of its Diagnosis." *Jl. de Med. et Chir.*, Jan.

For want of space the conclusion of this Retrospect is held over until our next. The subjects being Surgery, Midwifery, Diseases of Women and Children, Medical Jurisprudence, Hygiene, and Therapeutics.—Ed.]

Transactions of Societies.

THE SURGICAL SOCIETY OF IRELAND.

The Society met on the evening of Friday, 14th February.

The President of the Royal College of Surgeons, Dr. Kirkpatrick, in the Chair.

Dr. John Barker exhibited a

REMARKABLE TUMOUR

which had been sent to him last week by Dr. Ffrench Mullen, Assistant-Surgeon in the Bengal service. Dr. Mullen had sent it up to the museum of the College and was anxious to get Dr. Barker's opinion of it. The specimen was so strange, not only on account of its size (considering that it had been removed from the rectum), but from its contents, the size and folded state of the pedicle by which it was attached, and the peculiar nature of the cyst of which it was composed, that he thought it right to ask Dr. Mullen to supply him with further particulars of the case in order that he might bring it before the Society. Dr. Mullen had kindly complied with his request and sent him the following account of the case:—

On the 2nd inst., at the request of my friend, Dr. C. Nicolls, the dispensary Medical officer here, I went to see for him a poor woman who had been confined on the morning of the previous day, having been attended in her labour by the district midwife.

I found the woman rather weak and very desponding. She said she had no sleep since the birth of her child, and had suffered a good deal from a pain in her side. She was, she said, afraid she'd never recover, as "something had come down from her." Before making an examination I ascertained the following facts regarding the patient. She was a stoutly-built, healthy-looking woman, æt. about 39, had had three children before, and had no unusual trouble at her confinements. For a month or so before this last, the fourth child, was born, she had suffered from severe diarrhœa and had been much troubled by piles. This last labour had been longer and more painful than any of her previous ones. Her child was born at full time, is well grown and well nourished. The afterbirth, which was shown me, came away all right and within the usual time. The pulse I found to be 85 and fairly well filled; respiration, 18—full and strong.

On examination I found the large tumour shown, protruding from the anus, and on passing the finger into the rectum, I discovered that the flattened band-like portion was continued up the gut much farther than I could reach, and that it was not in any way attached to the walls of the rectum, at least within the 3½ inches or so I could explore. The walls of the rectum and vagina were, so far as I could ascertain, uninjured. I confess to having felt and feeling puzzled as to what the tumour was and where it came from, and under the circumstances refrained from interfering with it until I should have had the benefit of Dr. Nicoll's opinion on the matter. On the following day, the 3rd, we saw the case together, and after giving it our best consideration, concluded to do no more in the woman's then weak state than remove all that portion of the tumour. if tumour it can be called, which lay without the anal sphincter, and this accordingly was done. A strong ligature was passed round the tumour as close to the anus as possible, and then a single cut removed the portion now before the Society. From the part removed about ℥iij. of dark venous-looking blood drained out.

As I have neither read of nor seen a similar case I refrain from advancing any theory or opinion regarding this, but content myself with simply laying before the Society the portion of the tumour removed and the above notes of the case for the hurried and imperfect nature of which I venture to ask your forbearance.

Dr. Barker proceeded to say that the contents of the tumour were of a sebaceous character and full of small hairs. He examined these in the microscope, and they polarised light, showed the central axis and epithelial characters of hair, but without bulbs. One portion of the cyst of the tumour was bony. There were also on the pedicle and along the tumour several small cysts, containing a clear fluid. The flattened pedicle, its folded-up nature, and the non-malignancy of the whole, struck him as very peculiar, and well worthy the attention of the Society. Dr. Barker stated that, in his opinion, there were three sources from which this tumour might arise. It might be a tumour from the upper portion of the rectum or the colon, or a mesenteric tumour which might have pressed itself through; it might arise from a portion of the contents of the bowel, which had become encysted; or, lastly, though very strange to say it, it might be an ovarian cyst. It was very like the ovarian cysts in the Museum, three of which were now on the table. A quantity of hair was often found in ovarian tumours. The cyst was sometimes bony, and generally full of sebaceous material. He was not aware of tumours containing hair being found in any situation in the body except in the scalp and its neighbourhood, or in the ovarium. He had examined carefully with the microscope the hair contained in this tumour and hair from the ovarian cysts in the Museum, and he found they were somewhat allied. There was one point that struck him as peculiar,—there were no bulbs in the hair found in this cyst, and in some respects it differed from adult human hair. He did not say this was an ovarian cyst, but it was very like one, and it occupied a very peculiar position. As a specimen of a tumour from the rectum he believed it to be unique. He had not heard whether the patient had recovered, but he would endeavour to obtain further particulars, and would bring the case before the Society again.

Mr. Kelly read a paper on

AMPUTATION IN TRAUMATIC TETANUS.

Which will be found *in extenso* at p. 201.

Dr. Morrison said he rose thus early to mention a case which bore strongly on the interesting communication just made by Mr. Kelly, as it was to him that Mr. Kelly alluded. A good many years ago, on Christmas Day, in the immediate neighbourhood of Newry, a boy, æt. 14, was firing at birds with an old rusty pistol which burst and took off the thumb of the right hand. He was seen soon afterwards by a medical man, who removed the two phalanges and dressed the wound as usual. All went on well till the tenth day, when tetanic symptoms set in. He (Dr. Morrison) saw him on the eleventh day. He was then labouring under the usual symptoms of tetanus, rigid muscles at the back of the neck drawing the head backwards, and the muscles of the lower jaw were rigid, as were also the pterygoid muscles. He had the peering eye, the peculiar countenance, and the difficulty of swallowing characteristic of tetanus. He was advised to come into the Newry Infirmary, and he (Dr. Morrison) was to be there to meet him at a particular time. He set out at the proper time, but on the way the horse which was drawing the vehicle in which he was seated ran off and threw him violently to the ground, causing a very severe compound fracture of the right arm. The bones protruded a couple of inches, and it was a very bad case. This happened within twenty or thirty perches of the hospital, and he was immediately carried in by three or four men. He was very cold, pulseless, perfectly collapsed, and had lost a considerable quantity of blood. He was immediately placed in bed, surrounded with warm blankets, and bottles of hot water were used, and the other usual means resorted to. In about an hour reaction took place, when there was a fearful gush of blood from the wound, Unfortunately, there was no medical man present from whom he could obtain advice or assistance. Pressure was made on the wound and a tourniquet put on the brachial artery. He told the father and mother that it was a desperate case, and that only for the lock-jaw he would immediately amputate the arm, and that he would be inclined to do so in any case, even under the circumstances, although, he added, there was scarcely a chance of saving the boy's life. The man said he was told the hand should come away, but he did not expect the arm would be taken off. However, he consented, and the boy was put profoundly under chloroform, and the arm was amputated. He bore the operation well, the chloroform had a profound effect, and he never awoke until the arm was perfectly dressed. He was then put under the influence of laudanum and Indian hemp, given in doses as much as he could bear. There was no particular change in the tetanic symptoms for three or four days; they were neither better nor worse, the rigidity still continued, but there were no spasms. He was nourished by thin custard, beef-tea and gruel, in which there was a good deal of whiskey. Although there was great difficulty in swallowing, he got as much as sustained him. On the fifth day the muscles were slightly relaxed; on the sixth day they were more so; he gradually recovered, and in a month after he came in he was discharged cured.

Mr. Tufnell.—You amputated for the second injury. Had the case come into you without the second injury, would you have operated?

Dr. Morrison.—I should never have thought of amputating.

In reply to Dr. White, Dr. Morrison stated that there were no tetanic spasms after the patient's admission, but he saw him in spasms before his admission, and before the occurrence of the second injury.

Dr. Fleming thought they were much indebted to the gentleman who had brought forward this subject, and to Dr. Morrison for his graphic description of the interesting case that had come under his notice. It was important in considering the question of amputation, that they should be satisfied whether the case was one of genuine tetanus in the true meaning of the word, or merely one of trismus. If the latter, were they to attach the same importance to treatment by amputation as if the case were one of tetanus? He should like to know the condition of the abdominal muscles, and whether the power of flexion and extension of the lower limbs existed in the case described by Dr. Morrison? Some years ago he (Dr. Fleming) brought under the notice of the Society the case of a boy who died under his care in the Richmond Hospital of tetanus arising from an injury of the scalp. The question was raised in that case by Dr. Adams and others whether it was genuine tetanus, because that affection very rarely arose from an injury to the scalp.

In reply to the President, Dr. Morrison said, when he saw the boy on the eleventh day the abdominal muscles were quite rigid. There was always great difficulty in deglutition. The neck was forcibly drawn back, but after he came into hospital he did not see any spasm. There was tremendous shock from the second injury. The muscles never relaxed or became more rigid until the fifth day after his admission. The tonic spasm remained, and there was great rigidity of the pterygoid muscles, and of the muscles of the lower jaw, and of the back of the neck, but although rigid, they were not spasmodic. Whether it was the tremendous shock he got when he received the second injury, or the amputation which took away the *fons et origo mali*, or our genuine friend Nature, that did the work of curing the tetanus, he did not know, but he had told them the exact nature of the case.

Mr. Kelly said that by giving the patient some ten or twelve inhalations of chloroform there was caused a relaxation of the muscles of the jaw, so far that they were able to feed him and give him medicine. If ether had been available he would have given it to him, inasmuch as it was believed to act as a sedative to the motor nerves. Within the week in which this case occurred two other cases occurred in the hospital tending to show the epidemic character of the disease, and in a fortnight another case occurred in the

Mater Misericordia Hospitals. As to Dr. Fleming's remarks, he thought, considering the very imperfect knowledge they had of tetanus, they might set aside the distinction he raised between tetanus and the minor form of the disease called trismus. Dr. Fleming remembered a case in which the question arose whether a man died from trismus or tetanus, but if the man died, he thought it placed both diseases on an equality. With respect to Dr. Morrison's case, he thought the second injury, the compound fracture of the arm, would increase the liability to death from tetanus. He regretted he had not gained more information on the question of amputation in tetanus. He was strongly inclined to have adopted that course in the case he had brought before them, and he should have liked to have had the support of his seniors in any future case in which he might think that proceeding advisable.

The **PRESIDENT** said that some years ago he met with a very extreme case of acute tetanus which followed the insertion of an issue over the sacro-iliac symphysis. The man was suddenly seized with the most violent symptoms of tetanus. It was at the time the late Dr. Hardy brought forward an instrument to use chloroform locally by blowing the vapour on the part. He tried that very fully. He had a regular dress of oiled silk made and confined the man in a vapour of chloroform, and tried inhalation as well. It had a remarkable effect in prolonging life. The symptoms were so relieved that the man was able to take food, and his life was prolonged for fourteen days, although the case was of so violent a character that he thought the man could not have lived more than two days.

Dr. J. W. **MOORE** did not know whether Mr. Kelly was aware that Mr. Charles Macnamara, of Calcutta, had published some papers on the treatment of tetanus by heroic doses of hydrate of chloral. He had found the most satisfactory results to follow from chloral given in forty-grain doses. He gave one dose in the middle of the day or towards the afternoon, and if that did not quiet the patient sufficiently, he repeated the dose or gave one late in the evening. With that remedy and the free administration of milk and eggs, he had brought through a very large percentage of his patients among the native population of Calcutta. From one point in Mr. Kelly's case, nothing but a most unsatisfactory prognosis could be drawn, and that was the height of the thermometer, which during one of the spasms read 104 dgs. Mr. Macnamara had found that whenever the temperature exceeded 104 degrees, it was unfavourable, but when a moderate height was reached—100 or 101—the chance of recovery was very largely increased.

Mr. **KELLY** was aware of the paper published by Mr. Macnamara, but he considered that a forty-grain dose of hydrate of chloral was far from being an heroic one, for he had himself given twice the quantity without producing a soporific effect. The cases which recovered under Mr. Macnamara's treatment were cases of idiopathic tetanus occurring in a tropical climate, and they all knew that the mortality in idiopathic tetanus was not so great as that in traumatic tetanus, and it was to the latter that he wished to direct the attention of the Society. As to the temperature, it would be interesting to know whether Mr. Macnamara made his observations during the spasm or during the periods of intermission. If made during intermission he (Mr. Kelly) would look on an indication of 104 degrees as giving no chance of recovery, but if that height was reached only during the spasms, the probability was that his (Mr. Kelly's) view would coincide with Mr. Macnamara's.

Mr. **TUFNELL** said he had used chloroform very largely in tetanus. Some years ago he brought before that Society a case in which a young man, æt. 18, was taking down a hank of onions, and the hook caught him between the little and the ring fingers, the injury resulting in an attack of tetanus on the eighth or ninth day after the injury. He kept this patient for six days and seven nights under the influence of chloroform, causing him to inhale it and douching him with it by means of Hardy's apparatus, allowing him to come from under its influence occasionally in order to give him concentrated essence of meat by the rectum; and that person perfectly recovered. Last year he had a case of traumatic tetanus in the City of Dublin Hospital, and the man recovered under the influence of chloral and chloroform combined. He also had a case of idiopathic tetanus shortly before, which recovered by the use of chloral. With regard to nicotine, he had used it in tetanus from a compound fracture of the radius, and that case recovered; but in all these cases the great thing was to support life, to keep up the individual so as to give the disease time to subside. After his experience of chloral, chloroform, and nicotine, he was inclined to give the preference to the combination of chloral and chloroform, the latter by vapour and the former by the mouth, at the same time supporting the individual by wine and concentrated essence of meat.

Mr. **KELLY** said there was another remedy in tetanus, viz., the active principle of the calabar bean, which had the physiological principle of destroying the connecting power of the afferent nerves.

Dr. **PERSSE WHITE** thought some one should bear testimony to the value of a remedy which he believed every surgeon present who had tried it in these cases had found to be most useful—he alluded to the preparations of belladonna. It was the remedy used by the late Mr. Hutton, who was an able surgeon. A few years ago he (Dr. White) published two cases of traumatic tetanus that occurred in his practice. Both made good recoveries, and he had seen them both within the last few days in perfect health. The practice followed by him in those cases was that of the late Professor Porter, under whom he studied, combined with that of Mr. Hutton. He began the treatment with calomel and opium, and if he had a case to-morrow he would not depart from that treatment, although latterly the junior men were beginning to ignore mercury altogether. After he had touched the gums he then followed up the treatment with the steady use of belladonna.

The Society then adjourned.

◆

MEDICAL SOCIETY OF DUBLIN.

AT the meeting on Feb. 12th, 1873, Dr. **HENRY KENNEDY**, read a paper

ON THE "ÆTIOLOGY OF ENTERIC FEVER,"

in which is object was to show that the cause of this specific type of fever lay more in the constitution of the individual than in the outward causes; more particularly dirt (taking this word in its widest signification) to which so much weight has been attached. He supported his views by reference to a number of well-known facts; and more especially to what occurs in typhus fever, which he observed was much more fatal amongst the middle and upper classes than amongst the lower. Yet no one ever thought of these being different fevers. Something analogous, too, he stated, might be observed in the different mortality of typhus in London and Dublin; for it was known and admitted that in the former this fever was much more fatal than amongst ourselves. The various epidemics, too, of fever presented very marked differences, as all present were probably aware. Thus, that of 1817-18 presented a marked contrast with the one of 1847-48, which some amongst us recollected well. In none of the instances could the differences be attributed to varied poisons; and the author thought there were very good grounds indeed for supposing that they were mainly due to the general state of health of the people at the time being. In the same way he looked upon enteric fever as an affection which derived its peculiar symptoms mainly from the constitution of the patients. For very many years he observed that persons attacked with this type of fever were apt to have a fine skin, and high complexion. They were often, too, gleer-eyed, and, if children, had spots on their head. Many cases, too, had come under his notice where there were scars on the neck, and in point of fact, they were persons who, under any circumstances, would be looked on as delicate. This delicacy seemed to the author due to the strumous diathesis, and this view of the subject went far in explaining most, if not all, the peculiarities of enteric fever. The author then went on to draw attention to the hæmorrhages, and duration of the disease, and dwelt at some length, on the peculiar character of the lung complication, which so often showed itself in the progress of the fever. This complication not only often resembled tuberculous phthisis, but it ran, in a certain percentage of cases, into that disease. A gentleman in England, whose name he forgot, had recently detailed some cases of this kind. Besides, too, the author had himself met cases where phthisis supervened directly on the decline of the fever. But it was worthy of remark that no such occurrence had ever come under his notice in connection with typhus fever. The author then detailed a case in which the sequence of events was firstly the establishment of phthisis in a very unequivocal form; then a lull in the symptoms for a year; then an attack of enteric fever, marked by three crops of the spots of this disease, and finally the recurrence of the symptoms of phthisis, running its course with great rapidity. He also alluded to another case, which he saw with Surgeon Rogers, where, two years before an attack of enteric fever, the patient had been threatened with phthisis, attended by pulmonary hæmorrhage. The author then drew attention to the great similarity of the morbid state found in the ileum and mesenteric glands of a patient dying of enteric fever, and of one dying of phthisis. For his part, he could not distinguish them. In conclusion, the author said if the view he had advanced should prove to be correct, it would have a very important bearing on the prognosis and treatment of enteric fever.

The **Chairman** said they were all very much obliged to Dr. Kennedy for the very interesting and novel view of fever which he had expounded. He (the Chairman) would be glad to hear the views of any gentleman present on the subject. He thought he could corroborate the statement that the occurrence of thesis after pure typhus is exceedingly rare. He had not seen it as frequently after typhoid fever as he had after typhus.

Dr. **Darby** said the question of fever was of such great importance, and he had seen such a large number of cases of it during his life, that he could not allow the paper read by Dr. Kennedy to pass without some observations from him. The question appeared to him to be "What is Fever properly so-called?" He believed fever to be a disease that must take its course and terminate independently of all treatment. They could not stop any fever, no matter what they did if it was fever. If it were only systematic fever—if it were connected with a *strumous diathesis*—if it were not accompanied with *febrile* symptoms, it was not fever properly so-called. Fever affected the constitution, the system, the frame, the whole being of the individual, it set in, ran its course, and terminated altogether independently of anything they could do. They could guide a person through a fever, and might modify the symptoms by treatment, but they could not by that treatment stop it for one moment before the proper time. No, it would go away and leave the person as if he had not any disease. It was not an organic disease. As to separating them into two descriptions, they must look upon the complications what they called accelerated appearance of the head and skin—they are very fine strumatic. The great thing for them to consider was whether it was idiopathic fever or a systematic organic affection, and he believed they had not as yet, notwithstanding all their efforts, come to a clear understanding upon that point. With regard to what Dr. Kennedy had said on the subject of hæmorrhage, they were continually worried on that point because they had a quantity of hæmorrhage in febrile affections, in many cases in which there was true fever, and also in many in which there was no true fever. He had known cases in which there was a deal of purgation, perhaps a little crepatosæ, and perhaps they would find none at all. Hæmorrhage occurred, and man went through what some might call pneumonia, others might say it was fever, and so on, but the great fact in his (Dr. Darby's) mind was that when the time came all the failings suddenly disappeared, and the patient got well or died as the case might be. But the distinctive mark he (Dr. Darby) would make would be that if it were a fever there was no reason for it to disappear irrespective of treatment. He did not treat him with specifics, they sustained him by keeping up the physical powers, and suddenly all these local symptoms would disappear and the patient would get well. He thought there was a want of distinction between specific and other treatment in Dr. Kennedy's paper. It was a very valuable one no doubt, but he thought it did not guide them sufficiently to enable them to form a practical idea from it. He believed that there was not a year passed over but the cases of fever brought before them presented some modification of the disease compared with those that had been previously met with. He believed that a hard and fast line could not be drawn with respect to these cases, and he was also of opinion that there was no special disease or special organic affection which would induce a Medical practitioner to be very hard and systematic in his line of treatment. He (Dr. Darby) did not believe there was a distinction between enteric and typhus fever, and he believed they would have a type of fever present of an epidemic character, whether persons were strumous or not.

Dr. **Eames** said he would like to know what was the meaning of thesis?

Dr. **Grimshaw** observed that in the present state of Medical science he thought it would be very wrong to accept such a term as fever. They must call typhus and enteric by some right name or else they must drop the term altogether and distinguish them as separate diseases. That there was a difference he was perfectly satisfied. There were a great number of predisposing causes and exciting causes which might give rise to fever of all kinds. A certain number of predisposing causes, not only predisposed patients to fever of every type, but exposed them to every form of zymotic and other disease. He did not think because typhus and typhoid occurred in the same room that it showed that they arose from the same causes. Fevers, and symptoms of fevers, might be caused by over-crowding or living over a cesspool, but there was no reason that these should be considered identically on that account. He had found out that those localities, which were the favourite haunts of fever, also produced scarlatina, and in some cases measles, but also small-pox and cholera were most prevalent, and as far as he could learn they were never free from diarrhœa. Thirteen houses had produced two kinds of fever, and in all those houses cholera and small-pox had occurred. In a locality, known as Gill Square, the inhabitants nearly all died during the last visitation of the cholera, and scarcely a month passed without a case from that neighbourhood entering the Cork Street Hospital. Dr. Grimshaw then referred to the case of the town of Guildford, which he considered one of the most remarkable on record. In that town there were two water supplies, one a high level and the other a low. The high level came from a low part of the town by means of pumping arrangement at the bottom of a valley, towards which all the drainage of Guildford gravitated, and the water was polluted with the sewage. The water was pumped up to the higher part of the town. The people in the upper part of the town got typhoid fever, and those who lived in the lower part were free from the disease. By some means the water supply was stopped, and the typhoid fever ceased until the water charged with sewage was again supplied to the townspeople, when it broke out again. Strumous diathesis was a very difficult question to deal with. He could mention there 134 cases of typhoid fever, and in every case the people drank sewage from their own houses. He knew an instance of a large commercial establishment, in this city which was divided into three buildings, all separated and detached from one another, and situated in separate streets. One of these buildings consisted of the rooms where the pupils attended to receive instructions, and the other two were buildings in which all the female pupils resided, and in which a large portion of the male pupils resided, but not all of them. Where the class rooms were situated a certain number of male pupils resided. Enteric fever broke out among pupils attending these classes; none of the females were attacked, although several of them had strumous diathesis, and although he treated several for thesis. The males were attacked, no matter whether they lived near the class-room or not. The males used a set of water closets which the females did not use. The males drank from a water supply not very far from the water closets which the females did not use. The males got enteric disease and the females did not. Unfortunately, the people who got enteric fever formed every variety of skin and completion. There was no marked distinction between strumous nor strumous diathesis, and as to the liability to disease, they should take a look over the whole population of the country and find out the relative proportions of these two classes.

Some further discussion took place, and Dr. Kennedy replied.

The proceedings then terminated.

◆

DUBLIN PATHOLOGICAL SOCIETY.

[SPECIALLY REPORTED FOR THE MEDICAL PRESS AND CIRCULAR.]

FEBRUARY 21st, 1873.

Dr. **Quinlan** said the first case which he had to bring before the Society illustrated the fact, that while injuries and diseases of an apparently trivial character sometimes cause death, yet persons occasionally go about, and discharge their daily work while labouring under an amount of disease which would apparently render the continuance of life impossible. The patient under notice had been originally a soldier, and had served in India for about twenty years, until being discharged from the army on account of ague, he came home to this country about the age of thirty-four. He then obtained the situation of butler to a very eminent citizen, in whose employment he lived for several years. Although evidently delicate, he discharged his duties punctually and without complaint, and waited at table within twenty-four hours of his death. The next morning his fellow servants, noticing him look very ill, informed his master, who sent at once for his family attendant, who pronounced him in imminent danger, and had him removed to St. Vincent's Hospital, when he was found to be suffering from low pneumonia and pulmonary consumption. When admitted he was rapidly sinking, and died, in spite of every effort, nine hours after admission. A *post-mortem* examination showed, in addition to the pneumonia, which was the immediate cause of death, tuberculosis of both lungs, particularly the left. Both lungs were extensively infiltrated with tubercle, and contained several small cavities—several of them in the bases of the lungs. The kidneys were congested, and showed the ordinary appearance of fatty degeneration. The liver was healthy. The spleen, notwithstanding the old ague, was not more than twice the usual size. The second case was a fungous growth upon the inner side of the leg, just below the knee, of a boy aged seventeen, who had been operated upon for necrosis of the tibia, and from which a large sequestrum of bone had been removed. It was about the size of an orange, and bled copiously when touched, but did not cause pain. Dr. Quinlan removed it by the écraseur in nine minutes: tightening the chain rapidly in the beginning, and then proceeding more slowly. There was a great tendency to hæmorrhage, which was arrested by tincture of muriate of iron. A microscopic examination under 400 × showed numbers of cells with compound neuclei and neucleoli, also candated cells. It appeared to be a growth which originally benign was degenerating into malignancy. Since the operation the patient did well.

The meeting then adjourned.

At the last meeting of the Dublin Pathological Society, on Saturday, March 1st,

Dr. Kidd, in the Chair,

Dr. Bennett exhibited a specimen of fracture of the base of the skull and of the colloid process, as well as peculiar dislocation of the shoulder joint.

ACUTE TUBERCULOSIS.

Dr. Yeo showed the lungs, spleen, and kidneys of a female, æt. 52, who had been sent from the North Dublin Union to the Hardwick Hospital. When in hospital her breathing was very rapid (140—158); she had delirium, quick pulse, high temperature, incessant cough, and dark-coloured expectoration. She died seven days after admission, having been sick ten days before she came to hospital. The clinical diagnosis was asthenic broncho-pneumonia. *Post-mortem examination.*—The lungs were dense, heavy, and inelastic, and were throughout thickly studded with hard grey or yellowish spherical granules, varying in size from that of No 3 shot to the smallest point visible to the unarmed eye. The liver was large, pale, and fatty; the spleen was very large, and filled with small yellowish grains, more variable in size than those in the lung. The kidneys contained a number of small whitish bodies, the greater number in the pyramids; these tubercles were considerably larger than those in the lungs or spleen. Dr. Yeo thought it a good example of acute tuberculosis—the lungs, spleen, and kidneys being stuffed with recent milliary tubercles.

University of Dublin.—The following degrees were conferred on the 25th ult.:—*Bachelor in Medicine:* Robt. Nickel Denning, Richard John Kinkead, Robert Francis Russell, Thomas Arthur Woods, Brownlow Rudinge Martin, Frederick Simon Young.—*Master in Surgery:* John Edward Meredith.—*Doctor in Medicine:* Francis Edward Clarke, Mark Antony Fenton, Reuben Joshua Harvey, Eyre Jevers, Richard John Kinkead.

REGISTERED FOR TRANSMISSION ABROAD.

THE
MEDICAL PRESS AND CIRCULAR
s published simultaneously in London, Dublin, and Edinburgh, every Wednesday morning. Price 5d. Post free, 5½d.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6
" IF PAID IN ADVANCE 1 0 0

*** Post-office Orders and Cheques to be drawn in favour of—
A. A. TINDALL, 20, King William Street, Strand, London, W.C.
A. H. JACOB, 23 Ely Place, Dublin.
MACLACHLAN and STEWART, South Bridge, Edinburgh.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIERE, Publishers to the Academie de Médicine, Paris—post free in advance, £1 6s. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLMER and ROGERS; Baltimore, by Messrs. KELLY and PIET; Philadelphia, by Messrs. LIPPINCOTT and Co., and DR. BUTLER, post free in advance, £1 6s., about six and a-half dollars; or direct from the Offices in this country for the same amount, by the new Post-office Order system.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 5, 1873.

RAILWAY INJURY.

A TRIAL has just been concluded in the law courts, Dublin, in a case of railway injury, which has attracted a good deal of interest, as the amount, £1,300 has been considered larger than the awards usually given in Ireland, and the Medical condition of the patient was keenly discussed. Substantial damages have been constantly awarded in England, and such examples must have doubtless had a good effect in sharpening the interest of the railway companies in the good conduct of their lines; thus, we find a farmer of 35 awarded £5,775, a wine merchant of 43 £6,000, a gentleman (no occupation) of 50 £3,500. In our edition for Jan. 22, 1873, we have, on the other hand, a case recorded by Mr. Morgan, where a surgeon just commencing practice was severely injured in a railway collision, and yet was awarded but £650 by a jury in Ireland. On referring to the symptoms detailed in his case, as still continuing after an interval of many months, the sum was indeed insiguificant. The subject of the trial just concluded presented symptoms which were somewhat unusual, more particularly as to the form of paralysis from which the patient was suffering, being, according to the evidence, nervous paralysis, which was probably curable, in contradistinction to muscular paralysis which is unfortunately so seldom so. The muscular nutrition seemed unaltered. The Medical evidence was not agreed as to the then condition of the patient, and as to possibility, as broadly stated at the trial, that the injury was not permanent and that the patient was not "shamming."

The plaintiff was a young man, aged 27 years, a native of Liverpool, where he carried on the business of a factor in agricultural produce and cattle. On the 6th of March last, while travelling from the fair of Castleblaney on the defendants' line, he received some injuries from an accident that occurred at Inniskeen, and he sued the company for damages, laid at £2,500. From the facts it appeared that on the day in question he had paid for the carriage of some pigs by one of the company's waggons, and that he himself travelled in the van of the goods train that met the accident. The case made as to his injuries was substantially that he had lost from paralysis the use of his left arm and left leg, and that he was permanently disabled; and he was carried into court by three men, for the purpose of giving evidence, being apparently unable to move his lower limbs. The defence was that the plaintiff was a trespasser on the line, and was not entitled to recover, this being founded on an allegation that he had forced himself into the van of the goods train, when he should not have done so. It was also further alleged that he was "shamming" as to many of the symptoms which he professed to labour under. On the part of the plaintiff, Dr. Callan, Dr. Parker, of Dundalk, and Dr. Banks, of Dublin, were examined; and on the part of the company Dr. Davidson and Dr. Pusey, of Liverpool. By consent, a Medical inspection of the plaintiff was made on Friday evening by Dr. B. G. M'Dowell, F.R.C.S., Mr. G. H. Porter, Surgeon in Ordinary to the Queen, and Dr. Brunker. Dr. M'Dowell, in his evidence on Saturday, stated that he had applied galvanic and other tests, and he believed that the patient was suffering from nervous paralysis as distinguished from ordinary paralysis. The former malady was curable; the latter was rarely perfectly curable. There was insensibility to pain in the left arm and left leg of the plaintiff, and some insensibility in the right side also. The muscles of the limbs were in their original condition, but the power of using them did not seem to exist, and Dr. M'Dowell was of opinion that the plaintiff had not the power of using left leg or arm. He, however, expressed his view that in the result the plaintiff would be cured. Mr. Porter concurred in the evidence given by Dr. M'Dowell, and added, that under any strong excitement the plaintiff might suddenly recover the power of motion. Dr. Davidson and Dr. Pusey were recalled, and adhered to the opinion they had formerly given, that the plaintiff had the power, if he chose, of walking; that they had originally considered whether he was affected with hysterical paralysis, and they considered he was not; but, even if he were, they differed with the other Medical gentlemen in this, that they believed the will only was necessary to be exercised by the plaintiff to enable him to move, and they disbelieved the idea that the power to move was not in the plaintiff if he chose to exercise his will. The jury found for the plaintiff £1,300.

The question of *permanent* injury is, doubtless, the great stumbling-block in the way of Medical testimony, and the source of such difference of opinion as is not unusually evidenced, and, as in such instances as we have just quoted a large margin must be allowed for the probabilities of cure, Juries must of necessity take these carefully into their consideration, and where there is such strong evidence as was produced in this case of the existence of so grave a condition as paralysis—be it nervous or muscular—the unfortunately injured person has a right to be dealt with on a scale of liberality proportioned in some way to the sufferings already incurred, and to the possible dark future which is before him.

A RECANTATION.

Political economy gone mad is the fever with which English legislators, "progressive" liberals, and materialists are now stricken. If we freeze and shiver for want of coal we are calmly informed that it is all *en regle* with the principle of demand and supply, and that governments cannot undertake to alter the channel of so great a tide; if we complain of being poisoned in our food and cheated in our pockets, Mr. Bright complacently deprecates our indignation with the assurance that traders must, on the immutable principles of political economy, be rogues, and that the public is their natural prey, with whose fleecing great governments cannot be expected to interfere. *Populus decipiatur!* The proverbial advice "Live horse until you get oats" is freely dispensed to the suffering Briton by Mr. Gladstone, while the paternal Government which we are adjured to admire satisfies starving families and ruined manufacturers by the assurance that they are credibly informed by Mr. Mill that the present relation of capital and labour is just as it should be and only to be expected, and that Governments must really not be bothered about the results of such grand and immutable principles.

As we entertain a profound impression that political economy strictly applied is, in many cases, a dangerous and mischievous delusion, and that the hobby is just now being ridden to death by newspapers and ministers, we receive with real cordiality a repentant convert—and no mean one —from that form of fanaticism to common sense.

The *Times*, in a leading article on Mr. Plimsoll's exposure of shipowners' rascalities, thus writes—"Enlightened by one hard lesson of experience after another, we are coming to see that human society cannot be held together by the laws of contract alone, and that *caveat emptor* is, after all, a maxim of very limited application—that seamen (If seamen, why not the innocent public?) are competent to judge of such matters, and have a right to throw away their lives if they please. It is high time for this assumption to be reviewed by the light, not of reason only, but of recent precedents."

When the *Times* publicly notifies its opinion that people who have neither the knowledge nor the means of protecting themselves ought to be protected by the Government of the country, we may hope that adulteration frauds or quack practice will no longer be shielded from punishment by politico-economical aphorisms.

THE EFFECT OF INCREASED BAROMETRIC PRESSURE ON THE COMPOSITION OF THE BLOOD.

The *Journal de Médicine and Chir. Prat.* has drawn attention to the experiments of Prof. Bert, who examined the effects of increased barometric pressure, as endured by submerged bridge-builders, divers, and pearl-fishers, and explained certain accidents common to such occupations, among others that of sudden paralysis following a rapid passing from very high to normal pressure.

An hypothesis of M. Bouchard, in his introductory thesis, has been justified by an experiment of M. Bert. It is quite possible, said M. Bouchard, that these accidents are due to a considerable disengagement of gas from the blood; as effervescence is caused in gaseous water on its return to normal pressure when the bottle is uncorked. The presence of gas in the blood was demonstrated by M. Bert as follows: a cat, submitted to a pressure of eight atmospheres and rapidly removed from it, was almost immediately struck with paraplegia. Autopsy disclosed a non-hæmorrhagic softening of the spinal marrow and *gas in the blood-vessels.*

"A practical conclusion from these investigations of M. Bert, applicable to occupations pursued under high pressure, is to supply, not pure air, but a mixture of air and nitrogen, in such a manner as to suitably reduce the pressure of the oxygen."

The "practical conclusion" appears to us a very unpractical and unstudied suggestion. The evolution of gas from the blood, if there were any such effect, would result from sudden diminution of pressure, which would not be influenced in the remotest degree by the admixture of nitrogen with the air. How, might we ask, are divers to work in an atmosphere containing less than its due quantity of oxygen?

Opportunity for the study of this question under the best circumstances exists at the present moment in Dublin, where a colossal diving-bell designed by Mr. Bindon B. Stoney, is in daily use for placing the foundations of a quay wall. This bell communicates with the external air by a large tube, which rises from the top of the bell to the surface of the water. This tube contains a double air-tight door. A workman desiring to go down enters the chamber between the two doors, and, the upper one being closed, communication with the outside atmosphere is shut off. Then the compressed air from the bell is admitted to the intermediate chamber, as slowly as may be necessary for the convenience of the occupants, by a valve; and when the pressure within the bell and the chamber has been equalised, the lower door is opened and the workman descends.

We have not heard that any ill result is experienced by persons who constantly work in this bell.

A singular effect of compressed air was experienced by the workmen employed under a pressure of about three atmospheres, in sinking the foundations of the Saltash Bridge at Plymouth, namely, an extensive cutaneous eruption, which would not yield to ordinary treatment. However, by shortening the time of exposure to pressure the men recovered their usual health.

An engineer at present engaged in submarine works informs us that at a depth of forty feet, corresponding to a pressure of about 20 lbs. per square inch over the atmosphere, the workmen experience no inconvenience whatever, the transition from the high to the low pressure being made generally in about one minute. From all the data at our disposal we are inclined to believe that by paying proper attention to the length of time the workmen are allowed to remain under pressure, and seeing that a moderately gradual transition is made from one pressure to the other, working in compressed air may be carried on safely to any depth heretofore attained.

◆

Notes on Current Topics.

The London Hospital.

WHO has ever visited the east end of our great metropolis and not been struck with that huge pile of buildings, the London Hospital? From one of moderate proportion it has increased, from time to time, as necessity arose, and funds were collected, until at one period of its history, not long since, it contained within its walls 615 in-patients. The excellence of its arrangements management is so well known that no word is necess on this point. Our object now is simply to draw at tion to the fact that this noble institution, which is only general hospital in a district containing nearly million inhabitants, chiefly of the poorest classes, is c pled to such an extent for lack of funds, that the erec of another wing has to be abandoned, and parts of existing structure will have to be closed unless a l sum be contributed forthwith. Last year there was excess of expenditure over receipts of £13,000, and estimated excess for 1873 is calculated at not less t £20,000. In view of this deplorable state of affair special general court of governors has been held, and urgent appeal made to the public for £100,000. True, t appears a very heavy item to ask for or to expect, but i absolutely needed to put the hospital straight, and sincerely hope the authorities will get it. Millionair here is a splendid opportunity for showing your phil thropy; a draft upon your bankers for the amount not make you much the poorer, but it will confer u thousands of your suffering fellow-creatures, such bless as will well repay your munificence.

Incontinence of Urine.

DR. LEONARDI (*Raccogletore Med.*, No. 4) mentions t he has successfully treated several cases of nocturnal continence in children by means of chloral hydrate doses of ten grains in water given before bed-time. T same remedy has been successful with some of English brethren.

Arsenical Wall Paints.

WE frequently hear of warnings as to the dangers of green colorations used in wall papers, confection ments, ladies' dresses, and artificial flowers, &c.

The following analysis of the wall paint used in children's hospital ward, shows some startling results, impress us with the extreme danger of these pleasing ments. The analysis is by Frederick John Barrett, F.C Pharmaceutist to the Wolverhampton and South Staff shire General Hospital, who states: A short time was requested to make a qualitative analysis of samples of a suspiciously brilliant green paint, which been used for colouring the children's ward of a large vincial hospital. A preliminary examination abundant proofs of arsenic in all three of the samp and the colours upon the walls were immediately orde to be removed.

About seven pounds of No. 1 powder (containing arse cum equivalent to 53·224 ounces of arsenious acid) h been used for painting a ward the walls of whic measured 910 square feet, so that upon each square foot there was Scheele's green equivalent to about 26 grains of arsenious acid. The paint, moreover, was readily removed by rubbing and by moisture.

Adulteration.

THE Report of the Commissioners of Inland Revenue, furnishes some curious revelations as to the adulteration trade, and the efforts that are being made to restrain fraudulent gain-seekers. While the percentage consumption of some items such as whisky and tobacco, will doubtless surprise some of our readers.

Taking the census of 1871 as the basis of the calculation, it is shown that the quantity of spirits actually drunk in the United Kingdom is sufficient for every man, woman, and child to have 0·574 gallon in England; 1·727 in Scotland; and 1·064 gallon in Ireland—the average being 0·781 gallon. The Commissioners direct attention to the fact that with respect to whisky, there has been a great change in public taste. Comparatively speaking, Irish whisky has not been, till recently, a popular beverage; but during the last two or three years it has risen in public estimation, and is now becoming a substitute both for Scotch whisky and brandy.

It appears that during the year 42,656,658 pounds of tobacco were cleared for consumption, and this quantity represents 1 lb. 5½ oz. as being consumed by every man, woman, and child in the United Kingdom. The revenue derived from tobacco amounts to about seven million pounds sterling, and the quantity used is steadily on the increase.

Adulterations were detected in many articles of daily use; thus the samples of tobacco examined amounted to 404 in number, and of these 271 were adulterated, the adulterants being starch, liquorice, gum, logwood, caramel, sugar and salt of iron.

The amount of adulteration ranged to 4 per cent., rice starch, 44 per cent. liquorice, and 5 per cent. gum. The gum was discovered in tobacco obtained at two manufactories in the north of Ireland; and the novelty of this detection consisted in the fact that manufacturers being aware that tobacco contained gum, appeared to have thought that any kind of gum could be added to tobacco with impunity.

Of 34 samples of snuff examined, 6 were adulterated with umber and lime. 1,267 samples of tobacco and 433 samples of snuff were examined for estimation of duty on drawback; and of 15 samples of chicory and coffee examined, 5 were adulterated with roasted biscuit.

Out of 134 samples of beer and materials used in brewing beer, 25 were adulterated with one or other of the following ingredients:—liquorice, caramel, foot-sugar, grains of paradise, salt, and copperas.

The lime and lemon-juice examined for the Board of Trade for the use of the mercantile marine amounted to 761 samples, representing 84,649 gallons; 126 samples, representing 14,208 gallons, were rejected, thus showing that about one-sixth of the juice presented for examination did not reach the fixed standard of strength and purity.

The 356 miscellaneous samples examined include perfumed spirit, methylated spirit, laudanum, and paregoric. It is thus evident that the authorities have a vigilant eye to the detection of the improper use of methylated spirit for medicines for internal use.

It is to be hoped that vigilance as to the latter application of methylated spirit, will prevent its use in the preparation of paupers' tinctures.

Unqualified Assistants in England.

The *Pharmaceutical Journal* has called attention to the tolerance which is shown by the Profession to the practice of employing unqualified assistants, who prescribe and discharge all the functions of a Medical practitioner, with the knowledge, and under the cover, of their employer. The *Journal* calls upon the Profession to act consistently, and while it denounces counter-prescribing by chemists, to discountenance unlicensed practice by assistants. There is some force in the taunt of our contemporary, and it is a question worthy of serious consideration to what extent a practitioner is justified in delegating the lives of his patients to an illegal practitioner. The case of the chemist and of the assistant differ, it is true, in so far that in the latter the Medical practitioner incurs the whole responsibility, and is almost as liable for neglect and incompetence in his assistant as in himself, while the chemist is responsible to no one but the law. The employment of unqualified assistants is, however, an undoubted abuse, tolerated only for reasons of private interest and jealousy, and we should be glad to see close restrictions put upon the system.

Mercurial Injections in Syphilis.

Staub (*Gazz. d. Clin.*, Dec., 1872) uses an albuminous solution of sublimate of mercury with chloride of ammonium, chloride of sodium and distilled water, to which white of egg is added. Each gramme of the liquid to contain five milligrammes of the corrosive sublimate.

Army Medical Department.

The grievance which the Medical service of the army has been so long murmuring against, has at length received some kind of definite acknowledgment by Mr. Cardwell, when alluding, in Parliament, to the army-estimates. Amongst the Assistant-Surgeons who have joined within the last ten or fifteen years the prospect of non-promotion, or of "stagnation," has been grievously felt, and the provisions in contemplation in the long-delayed, but it is to be hoped now forthcoming warrant, have been anxiously forecast. How far the remedy will be beneficial it would be premature to surmise, until the conditions and details of the warrant have been more generally known. Mr. Cardwell thus expressed himself on the subject:—

> "I wish to make a statement with regard to the Medical service of the army. The Surgeons, like the Artillery and Engineers, have been complaining, not of an actual, but of an immediately prospective stagnation of promotion. Large numbers were appointed about the time of the Crimean War and the Indian Mutiny, and while their professional brethren in the Indian service were receiving promotion after twelve years' service, they were looking forward to stagnation, even those who had had fifteen years' service. We propose that there should be reduced numbers in battalions and larger numbers on the staff, by developing the system of station hospitals, which must prevail in case of war, and is strongly recommended by the highest Medical authority in time of peace. Fewer officers will thus be attached to the regiments, and more will be upon the staff. This will lead to great improvement in the future Medical arrangements. We do not propose to have any more Assistant-Surgeons, but only Surgeons and Surgeons-Major; and another portion of the plan will be such as, while there is great objection to making an absolute condition, will enable a Surgeon to look confidently forward to becoming a Surgeon-Major after fifteen years' service, and in India will give him local rank after twelve years."

It is well to find that a tangible grievance has been thus admitted, and some attempts being made for its rectification.

Laurus Nobilis, Eucalyptus, and Carbolic Acid in Intermittents.

These four remedies have lately been proposed as substitutes for quinine in intermittent fevers. Nevertheless, intermittents continue their ravages, and at present quinine is not losing its hold on the Profession.

Prosecution under the Apothecaries' Act.

A CASE has been just decided in the Court of Queen's Bench, which indicates an activity on the part of the Apothecaries' Company of Ireland to establish their rights, and to protect the public from the dangers of the compounding of medicines by unqualified persons, and in this instance it would appear by one who had absolutely failed in the attainment of the necessary qualification. It is time, indeed, that the Apothecaries' Company should deal with others who are similarly compounding illegally, and it is to be hoped that this easy and important vindication of their rights will stimulate to more energetic action. The case is given in the legal report thus—

"The action was instituted by the plaintiffs to recover from the defendant two penalties of £20, late currency, for practising the art and mystery of an apothecary, without having obtained the necessary certificate from the Apothecaries' Hall, authorising him so to do, as required by the Act of the 31st George III., cap. 34. The defendant was the proprietor of two Medical establishments, one at Portrush, in the County Antrim, and the other at Coleraine, in the County Londonderry. He had lately presented himself for examination at the Hall, but was unsuccessful. There was no appearance for the defendant, and the case having been proved, verdict was returned for the amount claimed."

Fistula in Ano.

HUTE (*Gazz. M. Ital. prov. V.*, No. 373) employs an ethereal solution of iodine in fistula in ano which is more exciting than the tincture. Patients are not obliged to keep their beds. Has had several cures after one injection.

Potatoes.

THE following figures will be of special interest to our Irish readers, as indicating the rapid and vast decrease in the home production of potatoes. These statistics respecting the importation of potatoes are given in an official document just issued. In the month of December, 1870, the value of such importation was only £446; in the same month of the succeeding year the amount was £33,770; and in the month of December last it reached £343,367. In the year ended the 31st of December last the amount was £1,654,240 against £225,732 in the preceding year.

The Quack Fraternity.

ON Friday last the Society for the Suppression of Vice dealt the most decisive blow against public indecency, which it has been our lot to witness. For years past there has existed in London a so-called anatomical museum for gentlemen (?); it was started by the notorious Dr. Kahn, who soon made a gigantic fortune by the speculation, and retired just in time to save a transference of his person from the ease of a pretentious house and a pair-horse carriage, to one of Her Majesty's most uncomfortable establishments. A few weeks since the Society prosecuted his representatives, and succeeded in obtaining an order for the destruction of his indecent books. Last week another raid was made, the museum mulcted of forty cases of wax models, and the wretched place closed—we hope for ever. Having frequently drawn attention to this foul blot, we are surprised action has been so long delayed; however, we congratulate the Society upon its success, and hope there will be no lack of funds to stay the tide of warfare it has undertaken against one of the greatest of all social evils.

The Recent Death at Exeter.

FROM a number of letters on this subject, we print important one from Mr. Woodhouse Braine, who quo one from the Hon. Secretary of the Odontological Soci every word of which we endorse.

In a late leader on the subject we expressed our appro of all that was done on the occasion, and may here rep that we feel the deepest sympathy with our brethr who met with an occurrence that might happen to one of us.

Cundurango.

THIS drug which was forced upon the American mark as a speculation, has long since been proved—as o readers are aware—utterly valueless for the purpose f which it was so loudly praised, the cure of cancer. D Andrew, Professor of Surgery in the Chicago College, h pursued a series of investigations into its action u ulcers, and reports very favourably upon its efficacy. conclusions are as follows :—

1. Cundurango has no equal in the materia medica i power to increase the growth of granulations, and haste cicatrisation of ulcers.

2. It seems probable that not only external ulcers, chronic abscesses and some fistulas, may be benefited by may improve lumbar abscesses, for instance.

3. It probably may prove a valuable adjuvant to the t ment of ulcers of the nasal passages, of ulcerative caviti the lungs, of ulcers of the mucous membrane, of the bow the cervix uteri, &c., and possibly of all ulcerative and p lar skin diseases.

4. The growth of granulation cells is the same pro whether seen on the floor of an ulcer, around a fractured in the form of a provisional callus, or in the plastic eff which glues together the lips of a wound healing by fir tention. It is probable, therefore, that cundurango, giv preparatory treatment, may greatly favour the succ cutting operations; and administered after surgical acci may promote the union of fractured bones, and the heal open wounds and burns.

5. Cundurango acts favourably in soft chancre (cautery), and on the ulcers and eruptions of tertiary syph

6. My experiments on hard chancre are not yet exte enough to be decisive, but, as far as they go, they tend t idea that cundurango has no influence on hard chancre, n the earlier eruptions of secondary syphilis.

7. The remedy has not produced, under my observa any effect on the growth and progress of cancerous tu It, however, often diminishes the pain and the disch and, if the tumour has been excised, hastens the healing o wound.

8. Cundurango generally increases the appetite, di constipation, and acts on many patients as a very pow general tonic.

No. 6 Sixteenth Street, Chicago, Ill.

Septicæmia.

FURTHER examination into the question has been m at the Academie de Médicine. In the two first series experiments animals were inoculated with human bl and also with ox-blood, which had been heated several hours. The blood of these animals in turn w capable of being inoculated on others. The results we various, but in all were more or less intense; several di with varying rapidity, others survived.

In another series of experiments the blood of a patien suffering from typhoid fever, which was found to contai vibriones was injected, and most of these animals died.

In another series the blood of a syphilitic child wa injected and gave similar results. On the other hand, when water only was used the animals recovered. On *post-mortem* examination the animals showed various internal affections, congested lungs, spleen, liver, &c., &c.

A Rock of Offence.

Having on several occasions devoted space to plead the cause of the Hospital Sunday movement, and its general adoption throughout the country, we feel justified in protesting against the very questionable paragraph now going the round of the press from *The Rock* newspaper. The paragraph is headed "Proportionate Gifts," and contains the relative amounts contributed by various religious bodies in a town where the movement has been recently started. Of course no one can gainsay what is so generally acknowledged, that in the United Kingdom the greatest amount of wealth lies amongst that portion of the community professing the faith of the Church of England; it is, therefore, to say the least, most uncharitable for the conductors of a leading paper belonging to that body to make invidious comparisons and give the percentages of voluntary offerings of the different bodies in a cause which is not, and cannot be sectarian in its dispensations. Such comparisons can do no possible good, and much ill-feeling may be engendered thereby. We trust, therefore, that the objects of this excellent movement may not suffer, or the flow of charity be checked by such narrow-minded paragraphs as that against which we feel it a duty to protest, and we look for the most liberal interpretation of our remarks to the conductors of all sections of the religious and lay press.

Treatment of Chilblains.

Ferd. Rhien strongly recommends, from actual experience, the following method of treatment, which he has employed with the most satisfactory results: 30 grammes of tannin are to be dissolved in about 200 cub. centim. of water, and to the solution is to be added 3 grammes of iodine dissolved in 50 grammes of spt. vin. The mixture is then to be diluted with water so as to form 1½ litre. The solution, when about to be used, is to be put in a vessel on a clear fire, and the affected part placed in it while cold, and kept in it until the fluid has become unbearably hot, when the part is to be dried by the heat of the fire without using a towel. The same fluid may be used several times. There should not be sufficient iodine to stain the skin, and if the skin be broken an excess of iodine is to be especially avoided. The first application, it is stated, will give the greatest relief, and three or four usually suffice to effect a cure.—(*Apothek, Zeit. Nr.* 41, 1872).

Centenary of the Medical Society of London.

Mr. T. Bryant, as this year's president of the oldest Medical Society in the metropolis, has issued a circular on its approaching Centenary, in which he states that it has been decided to enlarge the constitution of the Society and to make it more widely useful. For these purposes it has been determined—

1st.—To invite the leading provincial members of the Profession and of the Naval and Military Services to become Fellows of the Society; to give them, in common with all other Fellows, a part in its administration; and to make them equally eligible to all its offices.

2nd.—To publish the proceedings of the Society, including an abstract of all papers (not lectures) read at its meetings, and the pith of the discourses.

3rd.—To render more available their well-known valuable library, and to make arrangements by which new works and periodicals will be supplied for the use of the Fellows.

4th.—To provide a room in which papers and periodicals of general literature will be found, and where Fellows may consult, converse, and correspond.

The new rooms of the Society enable the Society to fully carry out these measures; and we wish them every success in their efforts. The Centenary Dinner takes place on Saturday next, the 8th inst., at Willis's Rooms.

Ophthalmological Curiosity.

M. Chautran, of the College de France, has recently made some experiments as to the regeneration of the eyes of crustaceases; after destroying the eyes of young crabs new ones are produced, and in the case of those more matured new eyes are also formed but more slowly; they may be reproduced, deformed, or even two may be formed in place of one, as remarks our correspondent, "man is, unfortunately, refractory as yet to this mode of regeneration."

Dr. Robert Liveing will lecture "On Elephantiasis Græcorum," at the Royal College of Physicians of London, on March 7th, 12th, and 14th, at 5 o'clock. Members of the Profession will be admitted on production of their cards.

The Royal Irish Academy will meet on Saturday, the 15th March, being their stated annual meeting, for the election of President, Council, Officers, and Honorary Members.

A Russian journal states, as one of the results of a recent commission issued by the Government, that upwards of 300,000 head of cattle have been lost annually by the cattle plague.

From observations made on a case of pleuritis with effusion at the *Hôpital St. Antoine*, it would appear that after the operation of paracentesis is performed, there is a considerable rise of the temperature of the body.

A great scandal is spared the Profession by the fact that the man Pearson, who now stands charged with publishing a most indecent libel against a lady, was long since deprived of his diploma, and has, therefore, no claim or title to be called surgeon as in the indictment.

The Medical officers of the French army quartered in Paris and Versailles have now established among themselves a society for the discussion of professional and departmental subjects. Their *organ* is the *Bulletin Médical Militaire*, published as a supplement to the *Bulletin de la Réunion des Officiers.*

M. Clerc communicated to the Congress of Friburg lately a case of transmission of aphthosa disease from the animal to the human subject marked by a stomatitis named *surlangue*, and accompanied by inflammation of the matrix of the nails. The case was that of a young girl in a district where the cattle were affected with aphthosa disease. She got coryza and stomatitis aphthosa, with ichorous and fœtid discharge from the finger and toe-nails, and was several weeks in process of recovery.

May not foot and mouth disease, cattle-plague, &c., be similarly related in the human subject?

Last week Sir James Paget was called in to consult with the physicians in attendance on the German Ambassador. Sir James performed the operation of tapping, and up to the time we go to press the patient was progressing quite as favourably as could have been hoped.

At the Royal Medical and Chirurgical Society on Tuesday, Feb. 11th, 1873, Geo. W. Callender, F.R.C.S., Surgeon to St. Bartholomew's Hospital, brought forward a case of removal of a needle from the heart—recovery of the patient. The history was that of a man who for nine days followed his ordinary occupation, in pain and with discomfort, having a needle fixed in the tissues at the apex of the heart. On the ninth day, in consequence of his statement and in view of the pain he was suffering, an incision was made over the fifth intercostal space, and the broken eye of the needle was found on a level with the intercostal muscle. This extremity was seized, and the foreign body was withdrawn. The patient recovered without an unfavourable symptom. With this history the exact position of the needle in the wall of the chest was given, as also that of its probable position in the heart; the movements of the foreign body, caused by those of the heart were figured, and their measurements were added.

◆

Correspondence.

THE LATE DEATH WHILE UNDER NITROUS OXIDE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Your journal of the 19th contains a letter from Mr. Denham, of Southsea, on the subject of the late case of death after the administration of nitrous oxide; and as I happen to have been the reader of the report, which enabled that gentleman to rush into print and make unkind insinuations, perhaps you will allow me to correct one or two of the numerous blunders contained in his letter. Mr. Denham writes in a satirical way of "Exeter dentistry," and as I was naturally anxious to see what his opinion was worth, I referred to the "Medical Directory," and found that he passed the College in 1829, a period at which dentistry was not taught in the schools, and when, in all probability, if Mr. Denham chanced to get an occasional tooth to pull out, he did it with the "key." From the same book I found that he is the editor of a local newspaper, a member of the Inventor's Institute, and the writer of an article entitled "The Queen, the Parliament, and the People." These honours scarcely give him a title to criticise a dental operation of any kind, much less enable him to understand the course pursued by Mr. Browne-Mason, a course of practice which was fully approved of by the Odontological Society of Great Britain, a society which numbers among its members most of the leading London dentists and many Fellows of the Royal College of Surgeons, but which, perhaps unfortunately, cannot claim the honour of having in its ranks a single member of the Inventor's Institute (whatever that may be). I shall be happy to read what Mr. Denham has written about "The Queen, the Parliament, and the People," but I cannot think it will be so amusing as his communication on dental surgery, for in the middle of his letter to you he actually mistakes a woman for a man, writes of her in the masculine gender. Mr. Denham says, "Of true surgery it is an axiom not to do more than is necessary." In this I agree with him, and say that he has misunderstood the operation from beginning to end, for the method of operating adopted by Mr. Browne-Mason consisted in removing those diseased fangs which acted as foreign bodies, *leaving the surrounding parts undisturbed.* How different is the following letter from the Odontological Society to the uncourteous effusion of Mr. Denham:—

"Sir,—Mr. F. Woodhouse Braine having fully reported to the Society, at its meeting on Monday, 3rd inst., the particulars of the unfortunate accident which has lately occurred after the administration by you of the nitrous oxide gas, the Society desires me to express to you their full conviction that the accident was one over which you had no control, and that no blame whatever can be attributed to yourself. At the same time they desire me to offer you their cordial feelings of sympathy under the circumstances, and their regret for the painful position in which you have been placed.

"I am, Sir, yours very truly,
"Edwin F. Lane,
"Hon. Secretary."

I can only add that I trust Mr. Hempson Denham will show, by his silence in your columns, the regret which he should feel at having published such a letter.

Believe me, Sir, yours obediently,
Woodhouse Braine, F.R.C.S.
56 Maddox Street, W.

NITROUS OXIDE DEATHS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—There are few men now in London who have watched conscientiously so many patients under ether, chloroform, and nitrous oxide, as it has been my duty and continued opportunity to have done; yet, according to Mr. Sewell, in your issue of the 19th February, it would appear I have set myself to differ in opinion, misrepresent, and misreport everything connected with the dentist's gas, because recent facts have led many persons to alter their idea of its safety.

I made no mistake about four deaths from nitrous oxide; it is your Correspondent's want of knowledge of the subject: a man's opinions are not "worth less" because he sees fit to alter them, having seen further into the general facts; my impressions were stated, and my explanation offered in vain, but it is idle to ask for any fair statement now in the chief journals, so my statement was only put in, as the newspaper thought it would serve some purpose of a public nature.

I have seen men alter their opinions, come right round, in fact, on catgut ligatures, the Dublin compression method in aneurism, ovariotomy, salivation in syphilitic phagedæna, bleeding in pneumonia, and half a score of other things, but, according to your Correspondent, when men make such conscientious alterations of opinion, something is worthless, meaning the man's judgment, and such impressions can have no value, of course to "scientific readers," possibly so, in this very new Wimpole Street school of thinkers, but then, Medical science obviously must stagnate, and can make no progress forwards.

What I wished to convey is this: I mentioned, and they were discussed at the Dental Society, Soho Square, at various times, three deaths from the "*gas*"—this Exeter one is the fourth; such occurrences have not unnaturally staggered the faith in it that one held two years ago. I have watched individually over ten thousand cases of chloroform without having had one death. I am quite aware and rejoice in it that there have been 58,000 cases at Soho Square (of the gas) without one death, though Dr. Richardson and the *Medical Times*, condemned it as the most deadly of all the suffocating agents. I watched a large number of these cases at Soho Square. These four deaths are sought to be explained away, that is all.

My impression just now is a very simple one, if it annoys your Correspondent it can only do so by its inherent truth or probability, namely, that, with all our towns now advertising "painless dentistry" (as a bait for the unwary), alone by the gas and many such dentists using other agents, there is now a want of certainty, and this Exeter case shows an imperfect mode of arresting danger, whereas in chloroform accidents, the scientific method of arresting danger seldom or never fails in saving the patient.

I admit even now that in proper hands the "gas" with all its failings, all the alteration of opinion about it, all this would-be infallibility or stagnation, all the explaining away of cases of death is wonderfully safe, indeed safer than methylene, ether, or chloroform, but that in the hands of the average dentist's assistants, as I said in the *Daily News*, the thing is like a ship without a pilot in a bad harbour, and the "gas" is not even as safe as chloroform.

I am, Sir, yours truly,
Charles Kidd, M.D.
Sackville Street, London, Feb. 28.

THE LATE MR. ISAAC BAKER BROWN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—May I trespass once more on your kindness, and be permitted, through your Journal, to inform the subscribers to the "Baker Brown Fund" that it is proposed that Mrs. Brown be permitted to draw from the balance of the fund (£217 17s. 10d.) £2. 2. weekly for the support of herself and three young children, respectively aged 8, 7, and 5, as well as to aid in the maintenance of a crippled daughter of Mr. Brown's by a former wife.

I beg to acknowledge the receipt of a donation of £5 from "An Old Patient" sent since Mr. Brown's death, by Dr. Nichol, of Denmark Hill.

I am, Sir, your obedient servant,
FORBES WINSLOW, M.D.

Cavendish Square, London,
March 3, 1873.

◆

Medical News.

Edinburgh University.— William Robertson, M.D., F.R.C.P., Edin., Benjamin Bell, F.R.C.S., Edin., and William Dumbreck, M.D., F.R.C.S., Edin., have been appointed Examiners of Medicine for the current year.

Sad death of a Surgeon.—On Sunday night Mr. Richard Meredith, M.R.C.S., Surgeon to the Dudley Union, drank a quantity of what he supposed to be brandy and water, but which afterwards proved to be laudanum; his son, who is also in the Profession, was present, and promptly administered the usual remedies, but without avail.

Donations, etc., to Medical Charities.—The following are announced:—University College Hospital, £1,000 from J. Pemberton Heywood, Esq.; from the Company of Fishmongers, 100 guineas; the Mercers' Company, 50 guineas; the Grocers' Company, £50; the Leathersellers' Company, 10 guineas; Mrs. Pett, £100; and from Mrs. Watson £50. The Worcester General Infirmary receives £500 under the will of Mr. William Jackson; from Mrs. Frances Osborne, of Cawthorpe, the British Medical Benevolent Fund, receives £100. The East London Hospital, has received £60, the proceeds of an amateur theatrical performance at Victoria Hall, Westbourne Grove, on the 6th of February. The late Dr. McWilliam has bequeathed £100 towards the funds of the Belfast General Hospital. The Bank of Ireland has received from the Cork Street Fever Hospital, Dublin, £20.

English Poor-law Medical Officers' Association.—The annual meeting of this association was held last week at the Medical Club, Spring Gardens. Dr. Rogers, who presided, in his opening remarks alluded to the anticipated amendment of the Public Health Act, 1872, which, however, had been dropped for this session. This he regretted, as well as Mr. Stansfeld's abandonment of the Hospitals' Dispensary Clause in that act last session. He thought that drugs ought to be found free of cost to all Poor-law Medical officers throughout the country, and he urged the extension of the system now in operation in London to the provinces (cheers). He concluded by announcing his resignation of the office of president, which he had held for nearly seven years. Dr. J. Lush, M.P., was then elected president, and Dr. Rogers, Dr. Brett, and Mr. C. Seeley, vice-presidents. The meeting then proceeded to discuss the sanitary and dispensary questions. Dr. Joyce moved, and Dr. G. R. Barnes seconded, "That this association viewed with satisfaction the tendency of rural sanitary authorities to pursue the policy of combination recommended by the President of the Local Government Board." Dr. Brett moved as an amendment, "That the opinion of the meeting was adverse to the amalgamation of large sanitary districts, and they considered that the Public Health Act could be best carried out by appointing Medical officers of their own districts, where possible." After a discussion, the amendment was carried. The following resolution was also adopted:—"That this association entertains a strong opinion that the establishment of public dispensaries in accordance with the recommendation of the sanitary commission and the Poor-law inspector's special report is necessary and desirable, and earnestly hopes that the government, notwithstanding their avowed attention of introducing no measure in the present session affecting the sanitary requirements of the country, may be induced, in view of the great distress among all classes of the poor, in a time of exceptional severity, to pass some measure having for its object the prompt and efficacious relief of sickness." A vote of thanks to the Chairman concluded the proceedings.

King's College Hospital.—On Friday last the Annual Court of the Corporation of the President, Vice-Presidents, and Governors of King's College Hospital, was held in the Board-room of the Hospital, General Wilbraham in the chair. It appeared from the report that the number of patients admitted into the hospital during the year ending 31st December, 1872, amounted to 1,792, being an increase of 252 over that of the preceding twelve months; 31,818 out-patients received advice and medicine; and 706 cases of midwifery were attended at the patients' own homes. These numbers represent distinct cases, and the majority of the out-patients attended the institution on many occasions before they were finally relieved. The receipts from subscriptions for the year were £2,001; from donations, £4,386; from legacies, £1,495; and from other sources, £2,831; making a total of £10,713. The receipts for the previous year were as follows:—Subscriptions, £2,094; donations, £5,781; legacies, £3,197; from other sources, £2,193; in all £12,265. The proceedings terminated with the usual compliment to the chairman.

Indian Medical Service.—List of successful Candidates at the Competitive Examination held at Burlington House on the 17th February, for sixteen appointments as Assistant Surgeons:—

D. Wilkie, 2,812 marks.
W. E. Battersby, 2,660.
A. J. Wall, 2,523.
R. Moodie, 2,411.
S. J. Goldsmith, 2,354.
W. B. E. Moynan, 2,319.
F. J. Twohy, 2,230.
A. A. Thomas, 2,216.
D. P. McDonald, 2,117.
O. Baker, 1,968.
H. Mallins, 1,950.
F. W. Wright, 1,899.
M. Robinson, 1,895.
W. R. Browne, 1,752
A. Leapingwell, 1,710.
J. S. Dill, 1,690

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this request.

All communications intended for insertion must bear the name and address of the writer; not necessarily for publication, but as a voucher of good faith.

NOTICE TO SUBSCRIBERS.—Subscriptions for the past year are now due, and will be thankfully received by the publishers. For England: A. A. Tindall. Ireland: A. H. Jacob. Scotland: Maclachlan and Stewart.

SUBSCRIPTIONS IN THE UNITED STATES.—A correspondent has drawn our attention to the fact, that some of the houses in the United States are charging the enormous figure of 15 dollars per annum (more than £3) for supplying this Journal to different parts of the States. We beg, therefore, to state that we shall be happy to supply the same regularly, post free, per annum, if paid in advance, for considerably less than half this amount, viz., six and-a-half dollars (about £1 6s. 0d.), either direct from our offices in this country, or through our recognised agents in the United States.

LAW RESPECTING PERIODICALS, NEWSPAPERS, &c.—1. Subscribers who do not give express notice to the contrary, are considered as wishing to continue their subscriptions. 2. If Subscribers order the discontinuance of their periodicals or newspapers, the publisher or publishers may continue to send them until all arrears are paid up, and Subscribers are held responsible for all numbers sent. 3. If Subscribers neglect or refuse to take the periodicals or newspapers from the office to which they are directed, they are held responsible till they have settled their bills. Sending numbers back, or leaving them in the office, is not such notice of discontinuance as the law requires. 4. If Subscribers remove to other places without informing the publisher, and their periodicals or newspapers are sent to the former directions, they are held responsible.

We are obliged to postpone several important articles, including Report on Diseases of the Throat, by Dr. Prosser James; continuation of paper on Cataract, by Dr. Jacob; Remarks on Dr. Mapother's Views of Eczema, by Dr. Myrtle; on Anthracosis, by Thomas Whiteside Hime, A.B.; &c. Reviews of Obstetrical Transactions of Edin., and several other works are also unavoidably held over. Letters on Secret Poisoning; the Proposed New Charity; the Coal Question; &c., are in type, and will be inserted as soon as space permits.

Mr. Nugent's letter has been sent to Dr. James, as we were unable to find space for it in our present number.

An Old Subscriber, Rugby, on paying his subscription, kindly remarks:—"Your publication is certainly entitled to the patronage of every Medical man, not only for its valuable contents, but *for its honesty* of purpose." We sincerely thank our correspondent; such expressions will do much to encourage us in the policy we have elected for the conduct of this Journal.

Dr. Phillips.—It is more within the province of publishers than editors. Consult one of the London houses.

COD-LIVER OIL AND CHLORAL.

To the Editor of the "Medical Press and Circular."

Sir,—Under this heading we observe a notice in your issue of the 26th Feb., referring to the combination of Chloral and Cod-Liver Oil as being recommended by the *Boston Medical and Surgical Journal*. Will you permit us to inform your readers that the combination of these important remedies is not at all a new idea, we having made the preparation and directed attention to it in the Medical journals quite two years ago, and also received several satisfactory reports as to its usefulness.

With this we have the pleasure to send a sample of the preparation for your inspection.

We are, Sir,
Your most obedient servants,
Savory and Moore.

New Bond Street, London, W.

Communications, with Enclosures, &c., have been received from Dr. Carpenter, London. Mr. Cole, C.B., Kensington. Dr. Smith, Huddersfield. The Director-General, India Office. Dr. Dureau, Paris. Dr. Dobell, London. Dr. Gibson, Broughton. Mr. Hyslop, Church Stretton. Mr. Dawson W. Turner, Liverpool, Dr. Feldmann, German Hospital. Mr. Jabez Hogg, London. Mr. Squire, London. Rev. Hume Rottery, Manchester. Mr. Sewill, London. Professor Mapother, Dublin. Mr. Tichborne, Dublin. Mr. J. Brown, Douglas. Mr. Feltoe, London. Mr. W. Parker, Bath. Dr. Thorowgood, London. Mr. Bryant. Dr. Griffiths, Dublin. The Secretary of the Medical Society of London. The Secretary of the Surgical Society of Dublin. Mr. Davies, Tenby. Dr. Langley, London. Mr. Harrington. Mr. Teevan, London. Mr. Calvert, Manchester. Dr. Hime, Sheffield. Dr. Myrtle, Harrogate. Dr. Marsden, London. Dr. Borchardt, Manchester. Professor Nugent, Montestown. Mr. Thornhill, Oxford. Dr. Pearse. M. Von Vogel, Leipzig. Dr. Chapman, London. Dr. Kidd, London. Dr. Abbott, Brigg. Dr. R. L. Johnson, London. Messrs. Savory and Moore, London. Mr. R. Hanslip Seis, Southwell. Dr. Dickinson, Pailton. Mr. J. Haughton, Duncannon. Dr. Jacob. Mr. Wright, Dublin. The Secretary of the India Office, Medical Department. Dr. Bell Taylor, Nottingham. Sir Henry Thompson, London. Dr. MacCormac, Belfast. Mr. Walker, Westminster. Mr. Bennett, London. The Registrar, Royal College of Physicians, London.

VACANCIES.

Hospital for Sick Children, Manchester. Resident Medical Officer. Salary £100, with board and residence. (See advt.)

Portsmouth. Medical Officer of Health under the New Public Health Act. Salary £450 per annum. Applications for the appointment to be sent in to Mr. S. J. Elliott, Portsmouth.

Medical Officer of Health for the united Districts of Stafford, Worcester, &c. Salary £800 per annum, to include all extras. Applications to W. L. Lowndes, Esq., Linley Hall, Bridgnorth.

Leeds General Infirmary. House-Physician. Salary £100 per annum, with board and residence. Also House-Surgeon, same emoluments. Address Mr. A. F. McGill, at the Infirmary.

Liverpool Royal Infirmary. House-Surgeon. Salary £100, with board. Applications to Mr. E. Gibbon.

Sheffield. Medical Officer of Health for the Borough, at a salary of £600 per annum. Applications to the Chairman of the Health Committee.

Sheffield. Public Analyst for the Borough. Salary £100 per annum. Application as above.

Herts and Middlesex. Medical Officer of Health. Salary £700 per annum, to include all extras. Applications to R. Pugh, Esq., Watford, Herts.

Richmond Union, Yorkshire. Medical Officer of Health. Salary £130 per annum. Applications to W. Hunton, Esq., Richmond.

Louth Union, Lincolnshire. Medical Officer of Health for the Rural District, at a salary of £375. And for the Urban District at £125.

Warwick County Lunatic Asylum. Assistant Medical Officer, at a salary of £100. Applicants must address Dr. Parsey, Hatton, Warwick.

Royal Free Hospital, London. Junior House-Surgeon. Board and residence. No salary.

New Ross Union, Duncannon. Medical Officer for the Arthurstown District. Salary £80 per annum. (See advt.)

APPOINTMENTS.

Biddle, C., L.R.C.P.L., Medical Officer to the Merthyr Union Workhouse and Infirmary.

Buck, H. J., L.R.C.P.Ed., Medical Officer and Public Vaccinator for Districts No. 3 and 4 of the Saffron Walden Union.

Busby, R. A., M.R.C.S.E., Resident Medical Officer to Queen Charlotte's Lying-in Hospital, St. Marylebone Road, W.

Dickinson, J., M.R.C.S.E., Medical Officer of Health for the Middlesborough Urban Sanitary District.

Garland, O. H., M.B., Visiting Medical Officer of the Leith Hospital.

Gell, A. S., M.R.C.S.E., Medical Officer of Health for the Southam Rural Sanitary District.

Gourley, S., M.D., Medical Officer of Health for the Hartlepool Rural Sanitary District.

Griffith, W. B., L.R.C.P.Ed., Medical Officer of Health for the Bootle Rural Sanitary District.

Hudson, T. W., M.R.C.S.E., Medical Officer for the Bootle District and the Workhouse of the Bootle Union, Cumberland.

Hutchings, H. E., M.R.C.S.E., Medical Officer of Health for the Canterbury Urban Sanitary District.

Johnston, J., M.R.C.S.E., Apothecary to the Sligo Dispensary.

Kempthorne, J., F.R.C.S.E., L.R.C.P.L., Medical Officer and Public Vaccinator for District No. 5 of the St. Germans Union.

Livy, J., M.D., Medical Officer of Health for the Borough of Bolton.

Love, J. H., M.R.C.S.E., Medical Officer of Health for the Wolverhampton Urban Sanitary District.

Lumb, R., M.R.C.S.E., Medical Officer of Health for the Whitehaven Urban Sanitary District.

Macfie, J., M.B., Resident Physician to the Royal Infirmary, Edinburgh.

Morrill, A. H., M.R.C.S., House-Surgeon to the Halifax Infirmary.

Oakeshott, J., M.R.C.S.E., Medical Officer of Health for the Horns Urban Sanitary District.

Powell, E., M.R.C.S.E., Assistant Medical Officer to the North Wa Counties Lunatic Asylum, Denbigh.

ACCIDENTS IN FLAP EXTRACTION OF CATARACT, AND THE METHODS OF AVOIDING THEM (*a*).

By Archibald Hamilton Jacob, M.D.Dub., F.R.C.S.,

Chief Surgeon to the Dublin Eye and Ear Infirmary, Ex-Ophthalmic Surgeon to the City of Dublin Hospital.

(Concluded from p. 178.*)*

I do not consider that a small escape of vitreous humour is of any importance, unless it escapes in advance of the lens. Some of my best results have followed a slight escape of fluid, which often surrounds a very ripe cataract, and I rather think that there is a certain advantage in the escape of such matter in small quantity, because it ensures that the anterior chamber, capsule and iris are perfectly clear of all scraps of softened lens matter.

Dressing.

The last point on which I have a word to say is the method of dressing the eye and finishing the case, and I apprehend that my views in this regard will be considered somewhat heterodox. I find, on examination of the various works, that while Stellwag, Macnamara, Bader, Wolfe, and Gross's surgery direct the eye to be padded with compresses and charpié, Mackenzie, Haynes Walton, and, in a modified way, Soelberg Wells advise it to be simply closed with isinglass plaister. Having tried both methods of treatment, in many cases I greatly prefer the old method. In my first operations I followed the compress and bandage system with the utmost care, and experienced the worst results from it. I had no means of judging of the condition of the eye except by the description of the patient's sensation, or by removing the dressings once or twice daily. I was hindered from applying an evaporating lotion or cleansing the edges of the lids of the hardened discharges; and, lastly, I believe that I facilitated suppuration and delayed the healing process by keeping the eye in a sort of poultice. I now uniformly confine myself to the application of a few strips of isinglass plaister over *both* eyes, the exclusion of light and the inculcation of the most perfect rest. At each visit I am enabled to judge by the appearances whether all is going well. I wash away with cold water any accumulated discharges, and if the case is satisfactory I refrain from removing the dressing for four or five days. Such a method of treatment is in every respect more simple and convenient, and as far as my experience goes much more satisfactory than the padding system which, if I did not know that it is approved of by surgeons of great authority, I would say was designed to obstruct cleanliness, confuse the surgeon, and hasten the suppurative process. I have just as decided an objection to the system of physicing, depleting, or starving the patient after the operation. In fact, I may say that, as regards the after-treatment of cataract, my practice is purely negative. I watch the patient carefully, feed him well without stimulation, make sure that he gets a quiet night's rest after the operation, and take care that his bowels are regularly moved, nor do I interfere at all unless pain or inflammation call for my intervention.

Experience.

I have already said that one of the objects of this communication was "to draw such a comparison as my experience enables me between the results of the old operation of Daviel, and the numerous recent modifications of it, of which many high authorities have spoken so favourably."

My own experience is as follows. Out of a large number of cases of operation for extraction of cataract performed during my connexion with the City of Dublin Hospital, in private practice, and more recently in the Dublin Eye and Ear Infirmary, I have systematic reliable record of 71 cases. Of these, 8 were spoon operations with small incision, and accompanied with iridectomy, and 7 were the modified linear extraction of Graefe, leaving 56 flap extractions by the old method. Of the eight spoon operations two resulted in total loss from sloughing and iritis, and four were complete recoveries; but in none was the vision as perfect, clear, and well-defined as in a good flap case. Not one of the eight could sew or read small print. Of the seven modified linear extractions only one was a loss, two were only partial recoveries, and the remaining four were perfect, but neither were they as perfect as good flap cases. Thus, it appears that of the fifteen cases with iridectomy three eyes were totally lost, four were only partial recoveries, almost all being injured by consecutive iritis, and eight were successes more or less perfect. Thus, I find that my success with these methods did not exceed 60 per cent. Of the fifty-six flap extractions, I had seven total losses from sloughing, ophthalmitis, or consecutive iritis. I had six partial successes, in which the patient had useful vision for large objects, and the remaining forty-three were perfect or nearly so, and were able to read ordinary print with cataract glasses. Thus, it appears that my complete successes with flap extraction were 77 per cent., as against sixty by other methods, and my total failures about 11 per cent., as against 20 per cent. lost in the modified operations.

These statistics are—as regards the operations accompanied with iridectomy—not large, but they are probably as extensive as they will ever be, for I am satisfied, not only by the results, but by an observation of the progress of the cases that such modifications possess no real advantage over the old flap extraction, and, at the best, never produce as perfect a result.

In 1863 Graefe published the results of 1,500 cases of Daviel's operation. Out of these he claimed only 65 per cent. of immediate and primary successes, and 15 per cent. more resulted from a second operation, making 80 per cent. as a grand total of perfect success. There was a total loss of 7 per cent. of the cases. In a later paper published in 1865, the same author gives another series of cases, in which he got 84 per cent. of perfect results, 11 per cent. of half successes, and a total loss of 5 per cent.; and in the same paper he states that, in his private practice the results were even better. In such cases he says he achieved 91 per cent. of perfect results, 6 per cent. of half successes, and only 3 per cent. of total loss.

When the same author first gave his experience of 300 cases of the modified linear extraction he claimed a proportion of 90 per cent. of immediate perfect successes, thus showing a marked superiority in the linear method. In a paper read by Dr. Loring, of New York, before the American Ophthalmological Society, it is pointed out that these superior results were arrived at by a simple process which must shake our confidence in such statistics. In the one case the standard of success was taken at a lower level than in the other, so that cases which were allowed as perfect successes in the linear method were set down as failures in the flap method. Dr. Loring says:—"We must take, in order to make the comparison a just one, 9 per cent. away, which would make a total of 84 per cent. of successes in the linear method against 84 of the second, and 91 of the third series of flap operations. Thus, we see that the balance swings, if anything, a little in favour of the flap operation. Even in Graefe's hand the results of each method are so nearly equal that it is still an open question which is the better, or, to say the least, there is no sufficient cause, as far as statistics are concerned, for the now almost universal belief that the linear is so much superior to the flap."

It is pleaded in favour of iridectomy as a concomitant of cataract extraction that it not only facilitates the operation, but it reduces the chances of subsequent inflammation, not only by getting rid of the inflammatory constituent, but by that undefined antiphlogistic effect to which is claimed to be the special merit of iridectomy.

In answer to these arguments I would observe that it is an unsurgical proceeding to get rid of an operative difficulty by cutting away the obnoxious member; that if the flap operation be carefully performed, neither prolapse nor injury of the iris need occur; that I have grave doubts as to the desirability of mutilating the iris for the sake of obtaining the very questionable benefits of an iridectomy, and that those benefits (if they really exist) appear to me to be more than counterbalanced by the infliction on the patient of a permanent deformity however slight, and the optical aberrations of an eccentric pupil. I do not fail to recognise the advantage of iridectomy to the operator, but I submit that the proper course for the surgeon is to overcome—as I believe he may readily do—manipulative awkwardness, rather than clear the obstruction out of his way by the summary use of the knife.

◆

ON ANTHRACOSIS.
(COAL-MINER'S LUNG, BLACK SPIT, &c.)

By Thomas Whiteside Hime, A.B., M.B., &c.,
Lecturer in the Sheffield School of Medicine, Medical Officer to the Hospital for Women, &c.

(*Concluded from p.* 130.)

The doubts which have been entertained as to the penetration of dust into the lungs, and its existence in those organs not only on the surface of the respiratory tract, but in the tissues, can be demonstrated as unfounded more readily in the case of Siderosis Pulm. (resulting from deposition of iron) than in anthracosis, because iron dust has more marked characteristics by which it can be recognised. Zenker, of Erlangen, the first who proved that iron-dust may be deposited in the lungs, in describing a case which he examined, states that the lungs were of an uniform brick-red colour, as well as the false membrane which covered them; very little discolouration existed in the bronchi, but the tissues of the lungs on section were found to be coloured on the surface. Microscopic examination showed that the red-coloured fluid which exuded from the cut tissues contained granules, which *chemical tests* proved to be oxide of iron. 1,000 grms. of the lung yielded 14½ grms. of oxide of iron to dilute hydrochloric acid; and, as might be anticipated, the parts of the lung where deposition had taken place were of a higher specific gravity than normal tissue. The deceased had worked for years at the manufacture of a kind of blotting paper, which was stained by rubbing the dry peroxide into the paper. Merkel, of Nurnberg, has recorded a case (*Deutsch. Arch. f. Klin Med.* b. viii.), in which the iron was found in another form, as black oxide. The deceased, who worked in an atmosphere highly charged with this salt, died of chronic pneumonia. In the grey-black sputa were found, before death, small black particles, some free, some enclosed in cells. Analysis proved these to consist of iron, and to be the cause of the discolouration. After death discoloured portions of the lung were examined by the distinguished chemist, Gorup-Besanez, and were found to contain depositions of iron, which must have penetrated from without, as the lung-tissue in question contained four times as much iron as the blood which supplied it. One more fact may be mentioned in support of what only arrant sceptics can doubt. Waldenburg (whose work on "Die Tuberkulose, die Lungenschwindsucht und Scrofulose" marks an epoch in the history of medicine) performed experiments for the artificial production of tubercle, which show how foreign bodies may be introduced into most distant organs. In order to establish his theory that corpuscular elements were introduced into the circulation from the substances which he employed for inoculation, and that they were concerned in the production of tubercle, he stained the inoculated substances with anilin-blue. The presence of the latter colouring matter in the pulmonary tubercle, produced by the inoculation, left no doubt as to the truth of his assumption. He performed the inoculations in the most various parts of the body, so that the pigment must have travelled a considerable distance to where it was ultimately found. This penetration of solid particles into the tissues must not be confounded with absorption. I think it is pretty clear that whenever a solid body, of whatever size, remains in contact with, *e.g.*, a mucous membrane, not so hard as itself, the solid body will penetrate at the point where it makes pressure, in the direction of least resistance; the tissues becoming gradually resorbed in the direction in which pressure is made. Subsequently tissue forms behind the body, and thus it becomes completely surrounded. The onward course of small particles will be of course much accelerated should they make their way into a vessel and be swept onward by the current until arrested by some obstacle.

In this manner I think the strange course which needles and other bodies sometimes take can be satisfactorily accounted for, which entering the body at one point make their exit at a spot very distant. In the case of absorption there is no destruction of tissue (by resorption) nor reproduction.

I only use the term Resorption in deference to general usage. Effused blood, *e. g.*, is really *resorbed* by a process identical with absorption. The disappearance of tissue owing to pressure is not due to resorption nor absorption at all, but is really a case of atrophy resulting from the interference with the nutrition of the part, the dis-assimilative process having become, abnormally, more active than the assimilative.

The *absorbed* fluid makes its way through the tissues in obedience to a physical law of a different kind,—viz., endosmosis. I think it is more than probable that a foreign body, such as dust, which makes its way into the digestive canal, as must frequently occur with workers at dusty trades, may penetrate thence into the tissues in the way I have described, so that the respiratory organs do not form the only portal. Slavzansky has shown that finely divided matter placed in the trachea will make its way into the pulmonary alveoli and tissue, and ultimately into the blood. His explanation of the manner in which this occurs is, that the dust enters through the capillaries and lymphatics. I think the general law I have stated is more likely correct. I have thought it necessary to be thus particular in proving that dust from without does enter the lungs, and have selected cases of metallic dust and others which have proved, *ad oculus*, its presence in them, because the nature and origin of the carbonaceous deposit found in anthracosis has been much disputed about. Having established this point I next proceed to describe anthracosis as it is commonly observed in this district, and I believe my remarks will be pretty generally applicable to others. The name was first applied in consequence of the black, carbonaceous deposit occasionally found in the lungs of some men and domestic animals, *e.g.*, the dog. Chemical analysis ascribes to it all the characteristics of carbon. Dresler asserts that the pigment of the bronchial glands is identical with vegetable carbon and exhibits the same reactions, being insoluble in acids, alkalies, alcohol, ether, and chloroform, and of a deep black colour. However, all possibility of error is removed by microscopic examination, which shows us, as in Traube's remarkable case, besides the discolouration, particles of coal-dust in the tissues, the exuded fluid, and in the alveoli. At the outset of the disease the lungs exhibit only small black spots, few and far between, while the alveoli also will be found dotted with black particles. The pleura presents a "marbled" appearance, and are commonly adherent in the more advanced stages. Later there will be found large black patches, the smaller bronchi being filled with the deposit, and ending abruptly where it begins. Thus, considerable islands may exist incapable of performing their respiratory function, though their structure may have undergone no essential change. In a still more advanced stage almost all traces of structure will be found to have disappeared, and the lung-tissue will be represented by a black-coloured mass, the appearance and feel of which are plain evidence of its nature, rarely excavated by caverns, which, when they exist, are probably the result of ulceration; although mere resorption of tissue, I believe, is not unfrequently the cause, as they will often be found in cases where no symptoms were ever shown of an ulcerative process having pre-existed in the lungs. The carbonaceous mass, though frequently offering no appearance of organisation in its structure, will be found to contain in combination a considerable quantity of organic matter; a fact quite in accordance with the known affinity of carbon for organic substances. It is asserted by Hirt that no black patches are to be found in the bronchi, but my experience is decidedly of an opposite character. The lymphatic glands may participate more or less in the affection, as will be seen by their colour; sometimes in aggravated cases they will be found enlarged and degenerated (Hirt).

During life the only distinct and unmistakable sign is *the black spit*, but of course this must have been of some duration to be of importance. The black-spit is not continuous, but intermittent, and is most commonly matutinal, being expectorated in the violent coughing-fits which generally occur in the morning. Before the disease has advanced far it does not probably originate below the trachea, but at a late stage it is brought up from the lungs. When examined microscopically this sputum will be found to contain considerable quantities of particles of carbon, some of them entirely encapsulated within cells, others partly outside and partly within, and others again free. In addition there will be found, according to circumstances, the usual *detritus*, which is of course not characteristic of anthracosis. The serious commencement of mischief is marked by temporary attacks of black spit, debility, and occasional oppression in breathing, especially in the evening, after work. This last symptom I have frequently noticed, and I think it important as showing that deposition has taken place, probably in some smaller bronchi, and that thus some previously debilitated lung-district has ceased to functionise. The cough now becomes severe, sometimes incessant, and the dyspnœa increases, the patient calling into play every accessory muscle of his debilitated and emaciated body.

The anorexia, which is an early and constant symptom, combined with the diseased condition, leads to general wasting, in which the inspiratory muscles alone do not participate. They always appear strikingly enlarged. Percussion and auscultation give evidence of the pathological changes, by the dulness and complete absence of all respiratory sounds in the chest. Hæmoptysis is not a constant symptom. Cardiac complications are necessarily induced by the interference with the pulmonary circulation, the right side of the heart being the earliest affected. Its action becomes "tumultuous," and the pulse small, quick, and hard. If the patient survive long enough, the effects of degenerated and over-worked heart will appear. Of course there can be no question of curing a patient in this stage; palliatives need alone be employed. At an early stage expectorants are most applicable: I frequently administer with good effects a mixture containing ammonia, squills, and senega. Narcotics should be sparingly used. I believe short hours, good pay, and good education would prove the best preventatives. Complete freedom from danger is not to be expected, but if a better system of *personal* hygiene existed, the risk would be infinitely diminished. If miners knew, and would practice, how to keep their bodies well nourished, by partaking of good food, avoiding excessive consumption of stimulants, keeping up their bodily temperature, and most scupulous attention to the state of the skin, much would be done to improve the difficulties of their useful but dangerous lot. The Turkish bath would be a great boon, and might readily be maintained beside every coal mine. Hot vapour baths could be kept going with the waste steam at a trifling expense, and would be of essential service, or it might be used to heat the water for warm baths. Within the mine the grand sanitary moments are, the constant supply of fresh air, the prevention of accumulations of unhealthy gases, and the maintenance of as dry a condition as possible in damp mines. It is to be hoped that the rising wave of sanitary reform will reach those humble but necessary contributors to our wants, who earn their bread not only with the sweat of their brow, but in ever-present danger. To teach them the highest pleasures of life may be impossible, but to teach them to *feel the want* of improvement would elevate the mind and be salvation to the body.

◆

REMARKS ON DR. MAPOTHER'S VIEWS AS TO THE NATURE AND TREATMENT OF ECZEMA.

By Andrew S. Myrtle, M.D.,
Consulting Physician to the Harrogate Bath Hospital, &c.

It would be one of the most fortunate discoveries of our time, could it be satisfactorily proved that the theory advanced by Dr. Mapother in his article, in the columns of this Journal for February 19th, on "Gout Poison" being the cause of eczema, was a fact—then our treatment of that many sided and most obstinate disease would be greatly simplified, and the action of specifics brought to bear on it, as they are so successfully on gout. I fear, however, we often behold things as we wish to see them, not as they really are, and that the proximate cause of eczema is still a matter of conjecture, its treatment necessarily empirical.

Of late years it must be allowed, that doctors and patients have exhibited a proneness to put down many irregular and trifling symptoms, as well as some graver evils to gout, as if gout had not enough to answer for already. A common remark is "My Doctor tells me 'tis Gout," perhaps "suppressed gout," when in truth it is brandy, or gluttony—venery or tobacco, or what is quite as bad, organic disease. Many skin diseases besides eczema, are also charged to the account of gout, and the public swallows it, in fact, rather rejoices in it. Gout is such a proper complaint, so very respectable, gives one a position in society, and points to at least one grandfather, who lived well, and after dinner did nothing but eat nuts and sip old port in an easy chair. Believing as I do that the gouty diathesis has no more to do with eczema than it has with hydrophobia, and that the treatment of the one is separate and distinct from that of the other, I desire to have an opportunity of giving my reasons as a practical dermatologist for dissenting from Dr. Mapother's axiom, "that constitutional eczema depends on the gouty diathesis, and should be treated according to the well known therapeutic indications observed in that condition." I shall take Dr. Mapother's facts in support of his argument in order :—

1. "The fact that uric acid and urates are found in the exudations and secretions of eczematous and gouty patients" proves nothing, as they are found in great abundance in all cases of recovery from acute diseases—in most chronic—in mental and emotional derangements, in short, wherever there is an abnormal waste going on in the system at large, or any of its parts.

2. "Increase of fibrine in the blood, its exudation and coagulation on the raw surface," in the majority of cases of eczema, there seems to me a want of fibrine in the blood, an excess of albumen and the coagulum on the surface and coverings, is mainly composed of albumen not fibrine.

3. "Both diseases are characterised by great tendency to œdema and desquamation,"—admitted—these conditions, however, present very different features in each, and in gout they have a much closer affinity to acute erysipelas than eczema.

4. "Equal proportion of hereditary cases in the two diseases, and their greater frequency among males," are gout and eczema more hereditary than other diseases? and are not men more liable to all diseases than women, not because they are men, but by reason of their circumstances and habits.

5. "Frequent concurrence of symptoms of gout, rheumatic gout, and eczema," this is not the experience of dermatologists, the greatest authority on the subject, Hebra, has distinctly stated that, he has observed no such connection.

6. "Aphorism of Hippocrates that gouty attacks are most frequent in spring and autumn, and the same may be said undoubtedly of eczema." Both statements are unsupported by facts, and have their origin in popular belief. Hebra, in speaking of eczema says, "I should rather look upon a severe winter or a hot summer, than on spring or autumn, as the season most injurious to the skin."

7. "Distant parts from heart and least vascular, most frequent seats of both diseases, as the *urates* are most easily deposited." I thought the favourite seats of eczema were the head, face, arm-pits, chest, thighs, flexures of arms, and legs, the very places were gout is never seen. When did any one see a case of eczema in ball of great toe, cushion of heel, or ball of thumb, these are the strongholds of gout again.

8. "The treatment proven to be useful in gout is usually successful in eczema," *tout au contraire* I say. In the former what are the usual remedies? Colchicum, alkaline, and neutral salts, rest, and low diet; in the latter the very opposite; tonics, especially iron, mineral acids, cod-liver oil, generous diet, even stimulants, with exercise in the open air. I trust I have advanced sound, if not scientific reasons, for venturing to express a different opinion to that so plausibly advocated by my Dublin *confrère*, my object being the prevention of a too ready acquiescence in the proposed plan of treatment, as I feel convinced were it adopted as the proper method of dealing with eczema, it would lead to great disappointment. As to the cause of eczema, most recent writers are inclined to put it down to faulty innervation, to debility, not to any dyscrasia. The nerves of nutrition somehow or other become disturbed, the capillaries lose their tone, congestion, serous exudation and infiltration take place, the tissue cells cannot perform their function aright, and, hence, all the local symptoms spring. Why certain situations should be selected in preference to others, it is impossible to explain, but that the disease depends on functional nerve derangement we can readily understand, when we consider how frequently it supervenes on exhaustion from loss of blood, grief and anxiety, night watching, exposure to cold, business bothers, over nursing, uterine affections, and improper food. We know also that injury to the trunk of a nerve is often followed by herpetic, hyperæmic and eczematous out-breaks in those parts where its terminal branches ramify, many such cases are reported as having taken place from wounds during the American war, and conversely, cases are reported where eruptions of a similar kind have been cured by division of the nerve trunk, proving most conclusively the important part nerves play in cutaneous disorders. In the treatment of eczema I have often been surprised at the freaks played by patients presenting similar appearances, how rapidly some recover under a certain plan of treatment, how useless or even irritating the same plan proves to others, how common in all to find, just as we flattered ourselves that the disease was cured, it return with increased activity; this has happened to me often under every form of treatment, and may in part account for the difference of opinion as to what is the best for this complaint; how we find one system almost universal in Paris, another in Vienna, a third in London. Yet, although we have such variance in the treatment, we find the symptoms pretty uniform, much the same with young, middle-aged, and old; with the weak and robust, little influenced by *diathesis*; affecting the strumous, gouty, rheumatic, and dyspeptic, very much alike. In its management it requires watching, as no exact rules can be

aid down as to what shall suit any individual case; there s nothing for it but experiment, and when we find one hing useless or hurtful we must try another. For my wn part, I have found in chronic cases more benefit from he application of coal-tar lotions, combined with mild atural sulphur water baths, and the internal use of halybeate waters, than from any other plan of treatment.

Harrogate, Yorkshire.

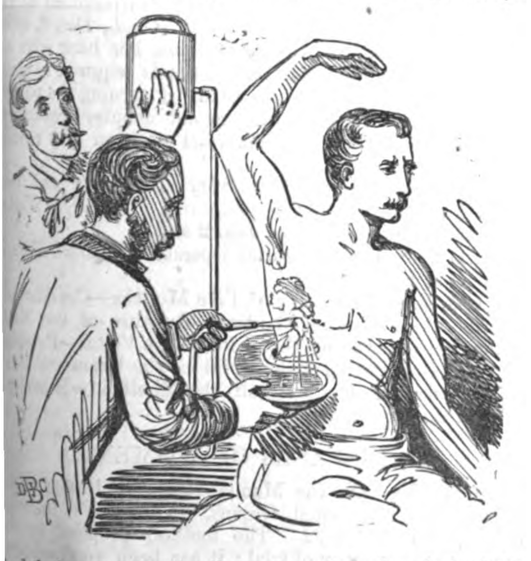
COMBINED IRRIGATION AND DRESSING APPARATUS.

By J. H. Porter,

[illegible] Regiment; late second in command of British Ambulance.

The illustration is intended to represent the irrigator nd tray used by the Prussian Medical officers in the ersailles Hospital during the late Franco-Prussian war, 870-71. While serving with the British Ambulance, I had the honour of being shown round the hospital of the [illegible]sailles by Dr. Stromeyer, Consulting Surgeon of [illegible] Corps, who kindly allowed me to see the [illegible] working of irrigator and tray. I was much [illegible] their convenience and usefulness, and have [illegible]med many hospital surgeons about them, who [illegible]ed me to bring them to the notice of the [illegible] Profession at home.



The irrigator is simply a can with two handles, one at [illegible] top, and the other at the side, somewhat larger and [illegible] than the ordinary "hot water" can. It has a [illegible] metal tube in the side, near the bottom, opposite [illegible] handle, to which is attached about five feet of flexible [illegible], and at its free end a pipe of wood, bone, or ivory attached, like an enema pipe. The can being filled [illegible] fluid it is only necessary to lift it in the air, and [illegible] the point of pipe towards the part requiring [illegible], when a gentle stream is produced; when no [illegible] required, lower can and turn pipe into it, or take [illegible] of tube round handle. A tap may be applied to [illegible] pipe, but has not been found necessary.

The tray is kidney-shaped, measures 17 inches long, [illegible] wide in centre, and two inches deep. It is [illegible] of block tin or pewter, from its formation is [illegible]pted to any part of the body, and, in conse-[illegible]vents wetting of clothes or bedding.

[illegible]ample of their adaptation, I saw them used for [illegible] extensive shell wound of chest and abdo-[illegible] was applied below the wound, which was [illegible]d, and not a drop of fluid reached the clothes or bedding. My own experience of the round edge of a basin or square side of the usual hospital dressing tray is that of inconvenience, and when many wounds have to be dressed sponges are difficult to procure. I trust, therefore, the tray and irrigator may on trial be found useful and convenient. The Prussian Medical gentlemen use the irrigator for washing out wounds during the operation of excision instead of sponges.

Richmond Barracks, Dublin.

Porter, George H.—The *Dub. Med. Journ.*, Feb., contains a valuable contribution to surgical literature from the pen of Mr. Porter, written with characteristic force and clearness and of great interest at the present time. Five cases are recorded. In the first there was a tight organic stricture of the male urethra, a large portion of the catheter was lodged in the bladder, the stricture was forcibly dilated, and the foreign body extracted. In the second case a portion of a gutta-percha bougie had broken off in the bladder, and a calculous formation had taken place round it; a modification of Allarton's lithotomy was successfully performed. In the third case nine inches and a-half of a gum elastic catheter had lodged in the male bladder, and had become surrounded by phosphatic deposit; a modification of Allarton's lithotomy was also successfully performed in this case. The fourth case was one of lithotrity for a small lithate calculus with an oxalate of lime nucleus, occurring in a patient, æt. twenty-six. The last case was also one of lithotrity for a small lithate calculus in a patient, æt. fifty-one. The paper is beautifully illustrated.

STUDENTS' COLUMN.

LECTURES ON HUMAN ANATOMY.

By Walter Rivington, M.S., Lond., F.R.C.S., Eng.,

Surgeon to the London Hospital and Lecturer on Anatomy at the London Hospital Medical College.

Lecture IV.

Ligaments of the Spine—Dislocations—Caries—Angular Curvature—Ligaments of Atlas and Axis—Injuries and Diseases of Atlas and Axis.

Gentlemen,—Having devoted the three last lectures to the Anatomical Characters of the Vertebræ I propose now to treat of the Ligaments connecting the Vertebræ, the different kinds of Joints met with in the Spine, the motions permitted at them, and the general features of the Vertebral Column as a whole. "There are between seventy and eighty joints in the Spine;" each with its own ligaments, and, "besides these proper ligaments, others" of an accessory nature "pass between the Vertebræ at different points (a). The Bodies, the Laminæ,

---

(a) Shaw, "On Injuries of the Back." "System of Surgery," vol. ii., p. 353.

the Spinous Processes, the Articular Processes, and the Transverse Processes, all have their separate connecting links, which will be considered in their order. The Ligaments uniting the first two Vertebræ with each other and with the Skull are peculiarly modified and will need distinct description; the Ligaments uniting the other segments are repetitions of each other, and can be described as a whole.

The *Bodies* of the *Vertebræ* are very securely joined by Anterior and Posterior Ligaments and intervening Discs of Fibro-Cartilage.

The *Anterior Ligament* is called usually the *Anterior Common Ligament* because it extends down the whole length of the column, and is common to all the Vertebræ from the Axis to *the Coccyx*. It is a strong, thick band, consisting of longitudinal threads of white fibrous tissue of different lengths superimposed upon each other, the superficial fibres being the longest, and the deepest fibres the shortest. When fresh it has a bright silvery lustre. It is attached intimately to the margins of the Vertebræ and the Inter-Vertebral Discs, loosely to the central parts of the Vertebræ. The deepest fibres pass between adjacent Vertebræ, the superficial fibres from one Vertebra to the fourth or fifth below it, the intermediate fibres from one Vertebra to the second or third below it. As this ligament serves to fill up in front the hollows of the Vertebræ, it is thicker opposite the middle than at the margins of their Bodies. From the Body of the Axis, where it is narrow and pointed, it gradually widens as it descends along the Spine until it reaches the Sacrum; from the Sacrum to the Coccyx it again narrows, so that it presents the appearance of two pyramids joined together by their bases at the upper margin of the Sacrum. It blends with the Periosteum, and serves to render the surface of the Sacrum and Coccyx agreeably smooth by preventing the natural asperities of the bones from injuring the Viscera and soft structures resting against them. Where it unites the Sacrum and Coccyx it has dwindled to a few scattered fibres, generally described separately as the *Anterior Sacro-Coccygeal Ligaments*, and on the lower part of the Sacrum and Coccyx it may not be distinguishable as a structure separate from the Periosteum.

The *Posterior Common Ligament* can only be seen by opening the Spinal Canal, and will best be demonstrated by removing entirely the Arches of the Vertebræ and the Spinal Cord enclosed in its Membranes. Theoretically, it should extend from the Skull to the Apex of the Coccyx along the posterior surfaces of the Bodies of the Vertebræ. The upper part, however, which reaches from the Axis to the Occipital Bone, will be considered with the special Axo-Occipital ligaments, and the lower part cannot be traced farther than the back of the Bodies of the Sacral Vertebræ, where it becomes lost and blended with the Periosteum.

Thus limited to the space between the Axis and the base of the Sacrum, the Posterior Ligament is seen to be broader above than below, the reverse of the Anterior Ligament, and to present opposite to the Inter-Vertebral Discs prolonged pointed, or dentated processes, separated by concave margins. It resembles the Anterior Ligament in consisting of several strands of fibres of different lengths, in being firmly united to the Margins of the Vertebræ and the Discs, thicker opposite the centre of the Bodies and scarcely attached to them there, if attached to them at all. Between this Ligament and the Bodies of the Vertebræ are large veins, which issue from the apertures which you have already seen on their posterior surfaces.

The Inter-Vertebral Fibro-Cartilages, Substances, or Discs, are highly elastic plates, corresponding in area to the surfaces of the Bodies, which they unite, and, therefore, of necessity, presenting individual variations in shape and size throughout the column. Their thickness varies also, for the Curves of the Spine are produced in great measure by their relative depth in front and behind. They are very firmly adherent to the surfaces of the Vertebræ, and attached intimately as we have seen to the Anterior and Posterior Common Ligaments. If a transverse section be made across one of the Discs it is at once evident that they are composed of two different substances, an *external* or *circumferential*, firm and fibrous, and presenting the appearance of concentric circles, and an *internal*, soft and pulpy, which by virtue of its elasticity rises up above the level of the other. Now these two parts, the Laminæ and the Pulp, fulfil different offices. Both are elastic, but the elasticity of the Pulp far exceeds the elasticity of the circumferential portion of the Disc. Both serve to connect the Vertebræ, but the Pulp in this respect has not a fraction of the importance of the Laminæ surrounding it.

The Laminæ have their edges directed upwards and downwards, towards the corresponding surfaces of the Vertebræ above and below. They are arranged concentrically and in such a manner that the fibres of one Lamina cross the fibres of the Lamina succeeding it. In all, the fibres run obliquely from above downwards, inwards in some, outwards in others. Thus, the fibrous plates present a succession of crucial ligaments. At the circumference they are composed mainly of fibrous tissue, internally of fibro-cartilage, cartilage cells, and interstitial fluid. In the centre the fibres become more irregular, the cells are more numerous, and the fluid is greatly increased in quantity. Professor Humphry denies the correctness of Weber's account of the circumferential fibres, which is copied from text-book to text-book, and which represents them as curved outwards towards the surface, and curved inwards towards the Pulp. In all the sections he has made he has found the fibres straight near the edges of the Vertebræ, and curved slightly outwards near the pulp. When compressed at any one spot this curvature is necessarily increased.

If you look at the surfaces of a Lumbar Vertebra you see that near its margin is an elevated rough circle of bone, while the centre is depressed and comparatively smooth. The circumference attaches the circumferential Laminæ of the Disc, and is rough to allow its fibres to bite the bone better; the centre corresponds to the Pulp, and is rendered much more smooth by a thin plate of cartilage adherent to it. From both parts the Periosteum is absent. In point of fact the Pulp constitutes an elastic ball, compressed on all sides, a cushiony pivot on which the Vertebræ move and rotate, and which infinitely diminishes the force of the shocks continually received and transmitted through the Spinal Column. You will comprehend these functions and the essential nature of the Pulp better if you compare it with the structures found in lower Vertebrates, and as I cannot improve, I will quote, a brief account given by a great master of Anatomical Science. "In certain fishes (*a*) the Spine consists of a cartilage made tough by ligamentous inter-texture. Ascending in the scale of animals we find the Cartilage forming the Spinal Column subdivided by cavities which contain a gelatinous fluid; and these cavities being surrounded with a strong but elastic ligamentous covering, nothing can be conceived more admirably adapted to give a springiness to the whole column. Still ascending, we discover that the bony matter becomes deposited between these cavities; and here the separate Vertebræ first appear. If two of the Vertebræ of the Great Shark be taken out together and the Sac between them punctured, such is the elasticity of the walls of this Sac that the fluid will be spouted out to a distance. In other fishes, as the Cod-fish (an osseous fish), the structure approaches to that of the Mammalia; the inter-vertebral substance is gelatinous. In the Whales circular concentric ligaments join the Vertebræ, and a small portion in the centre consists of a glairy matter. In Mammalia and in Man there are strong and distinct bones of the Vertebræ, and these are joined by a ligamentous cartilage, the outer circle of which is remarkably strong, and the centre soft and elastic. The toughness and strength of the exterior circle, and the soft condition of the centre, make a joint equivalent in action to what might be produced by a ball intervening between the surfaces; a facility of motion is thus bestowed which no form of solid could give, and yet the joint is so strong that the bone breaks from violence, but the ligamentous cartilage never gives way. When the Veterinary Surgeon casts a horse, if he be not careful to restrain him, he will twist himself with a force which will break the Vertebræ. It is a frequent accident in man, but the texture which gives mobility to the Spine never yields." The statement here made by Sir Charles Bell that the Fibro-Cartilaginous Discs uniting the Vertebræ never give way is too absolute, for cases now and then occur in which the Discs have been torn without fracture. If you will refer to the specimens of so-called "Dislocations of the Spine" contained in our Museum, about thirteen in number, in all but three the Body of one of the Vertebræ at the seat of displacement is crushed, fully accounting for any injury done to the Inter-Vertebral Substance. In one of the three remaining specimens (Gbb 19) there is slight splintering at the edges of the Bodies; in the other two (Gbb 10 and Gbb 14), both in the

---

(*a*) Myxine, Lamprey, Sturgeon.

Cervical Region, there does not appear to be any fracture whatever of the Bodies, the separation being due to rupture of the Fibro-Cartilages. Similarly, in a recent case of my own, caused by forcible flexion of the Cervical portion of the Spine, the fourth Cervical Vertebra was partially displaced forwards from the fifth without fracture. The Inter-Vertebral substance had been torn, but the Anterior and Posterior Common Ligaments remained entire. In Gbb 10, which is a displacement *backwards* at the fifth Cervical Vertebra, there does not appear to have been any fracture at all. The ligaments connecting the right Articular Processes are torn, and the Inter-Vertebral Substance lacerated. In Gbb 14 the displacement had taken place between the sixth and seventh Cervical, and only the edges of the Articular Facets were fractured. In my own specimen there is no fracture of the Facets, Arch, or Body of the fourth; the left Tubercle of the Spinous Process of the fifth Vertebra has been torn [illegible]

It is interesting to note that in Spinal displacements the upper part of the Spinal Column is generally carried *forwards*, and that in one of the specimens in which the Disc only has been torn, the Vertebræ above the seat of dislocation have been carried *backwards*. It is also worthy of observation that in some of the specimens, as in my own case, the Anterior and Posterior Ligaments remain entire; in others, where the violence had evidently been greater, one or both are torn across. But the Bodies of the Vertebræ are not liable only to fracture and crushing from force accidentally applied, they are often seriously affected by disease. The puny, ill-clad, ill-developed, half-starved offspring of our poorer classes, are prone especially to suffer in their bones and joints. A large portion of the compact tissue of the Shafts of the Long Bones perishes—constituting what we call *Necrosis*, or the Death of Bone; or the cancellous ends of the Long Bones and the cancellous tissue of other bones soften and disintegrate particle by particle, constituting what we call *Caries*, or *Ulceration of Bone*. Now the Bodies of the Vertebræ, made up of cancellous tissue and called hourly into use for the support of the frame in the sitting and standing postures, are rendered specially obnoxious to [illegible] when the laws of health are infringed. Disintegration takes place with or without the formation of matter or [illegible], and large gaps are made in the Spinal Cylinder. The upper part of the Spine, having lost its support, falls forward, a projection becomes visible behind, and Angular Curvature is produced. Rarely, the Intervertebral Discs are the parts chiefly affected, often the two suffer together, [illegible] the Bodies only melt away. On the table you [illegible] see two very interesting specimens. In one (Fb 3) the disease appears to have been mainly confined to the Inter-Vertebral Discs; in the other (Fb 7) the Inter-Vertebral Discs stand out prominently between the spaces now empty [illegible] once occupied by the Bodies of the Vertebræ. The best thing that can happen in such distressing cases is the union of the Bodies of the Vertebræ above and below the gap, granting the patient the loan of life with the discount of deformity (*a*).

The *Laminæ* of the Vertebræ from the Axis to the Sacrum are united by Ligaments which are formed of pure elastic tissue, and, having a yellowish hue, are called *Ligamenta Subflava*. Each Ligament is composed of two symmetrical halves, which together fill the interval between the Laminæ of the Vertebræ to which they belong. Each half extends from the Articular Process in front to the root of the Spinous Process behind, where its edge is contiguous to that of its fellow. The fibres of the Ligament are attached to the anterior surface of the Laminæ of the Vertebra above, about ¼th of an inch from their margins, and to the upper border of the Laminæ of the Vertebra below. Hence they are best viewed from the interior of the Spinal Canal, on the Arches which have been separated for the demonstration of the ligaments of the Bodies. The attachment of the Ligamenta Subflava to the anterior surfaces of the upper Laminæ is for the purpose of permitting the upper Laminæ to slide over the lower in extension of the Spine. The Ligamenta Subflava are thinnest in the Neck and thickest in the Loins. Existing naturally in a state of tension in the Neck and Loins, they preserve the curvature of the Spine, help to maintain the body in the upright posture, counteract the forward traction of the Viscera in front of the Vertebræ, and when the Column has been flexed by muscular action, restore it without effort to its original position. By this means is effected a large economy of muscular tissue and force.

The *Articular Processes* are united to each other by ligamentous fibres attached to the rough surfaces outside the margins of the cartilaginous plates which cover the articulating facets. These fibres being disposed circularly and loosely round the articulations are named *Capsular Ligaments*, and they are lined with a fine smooth membrane, called the Synovial Membrane because it secretes a viscid moisture known as Synovia, and vulgarly as joint-oil.

The *Spinous Processes* are connected by two sets of fibres, called the *Inter-Spinous* and the *Supra-Spinous*. The *Inter-Spinous* are so named because they are placed *inter—between*—the Spinous Processes as bands of white fibrous tissue, variable in thickness and strength, running between the opposite margins of contiguous spines. These Ligaments consist in the Neck of a few insignificant fibres near the roots of the Spines; in the Back of thin diaphanous triangular plates, and in the Loins of thick quadrilateral bands, occupying the margins of the Processes from root to tip. The *Supra-Spinous* are so named because they are placed *supra—over* or *above* the Spinous Processes, forming a cord-like ligament connecting their tips, and extending from the Occiput to the Sacrum. Where it lies over the Cervical Spines it is described separately as the Ligamentum Nuchæ, the mere rudiment of a strong elastic structure which in four-footed beasts plays so important a part by sustaining the weight of the head. It is stronger, broader, and more important in the Lumbar than in the Dorsal Region.

The *Transverse* Processes in the *Dorsal* and *Lumbar* regions are united by some irregular cords or bands of scattered fibres. The use of these ligaments connecting the Processes is obvious.

The *Capsular Ligaments* of the Articular Processes serve to maintain the Facets in apposition with each other without preventing the motions proper to the joints. They are often torn in Dislocations of the Spine.

The *Supra-Spinous* and *Inter-Spinous Ligaments* prevent separation of the Spinous Processes, and thus check forward bending; the *Inter-Transverse Ligaments* prevent the separation of the Transverse Processes, and thus check bending laterally. All contribute to the firm union of the osseous elements of the Spinal Column.

(*To be continued.*)

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, FEB. 25TH, 1873.

T. B. CURLING, F.R.S., PRESIDENT, IN THE CHAIR.

ON DISSEMINATED SUPPURATION OF THE KIDNEY SECONDARY TO CERTAIN CONDITIONS OF URINARY DISTURBANCE.

BY W. H. DICKENSON, M.D. CANTAB., F.R.C.P.,
Senior Assistant-Physician and Lecturer on Pathology at St. George's Hospital, Physician to the Hospital for Sick Children, etc.

IN this paper the author proceeds to describe the peculiar suppurative condition which is sometimes spoken of as the "surgical kidney," and is produced, as he shows, by the contact of unhealthy urine. Of all renal disorders, next to those described by Bright, it is the most destructive to life It may almost be said to form the natural termination of.

(*a*) Fb 12 shows some of the Dorsal and Lumbar Vertebræ involved in an Angular Curvature nearly at right angles. The Bodies of the Vertebræ, together with the Intervertebral Substances, have been entirely removed, and two others are extensively destroyed. Anchylosis appears to have been in progress.

Fb [illegible] shows complete destruction of the Bodies of two of the Mid-Dorsal Vertebræ, together with their Inter-Vertebral Substances. The Theca of the Cord is exposed, and a circumscribed abscess cavity, as large as an egg and with a dense wall, is seen in front of the diseased portion. Although the destruction of the Bodies is complete, so that a gap an inch and a half long is left, yet there does not appear to have been any Angular displacement stricture of the urethra, and is the especial danger which attends the use of the catheter and lithotrite.

The renal change which is always associated with signs of pelvic and vesical inflammation, and often with alterations of the gland dependent on wasting pressure and chronic vascular disturbance, essentially consists of a peculiar turgidity and friability of the renal structure, with the formation of small scattered abscesses, or soft yellow deposits antecedent to abscesses, throughout its structure. With these are usually seen conspicuous white lines in the cones, which are morbidly occupied straight tubes.

With this condition the microscope shows more or less dilatation of the straight tubes, distension of, or coagulation within, the blood vessels associated with them, and disseminated intertubular suppuration, the distribution of which is regulated by the course of the veins. (The microscopic appearances were illustrated by drawings which show the dilatation of the straight tubes; the irregular repletion of, or coagulation within, the vessels of the cones and the larger veins of the cortex; and the origination of abscesses around the affected vessels and throughout limited tracts of the intertubular tissues. The swelling of the intertubular tissue where thus unfiltrated by the new cellular formation was strikingly depicted in contrast with the slender network presented by the same structure in a part of the gland exempt from the change.)

Taking the structural changes in their mutual relation, the usual dilatation of the tubular exits, the morbid occupation of the veins, and the general absence of the origin of tubal inflammation, the nature of the process is clear. The disorder has its origin in the regurgitation of urine charged with morbific products. This occupies and generally distends the straight ducts, and thence enters the neighbouring blood vessels, and charges them with an infection resembling in its results that of pyæmia. This is distributed by the veins to the rest of the gland, sowing abscesses in their course, and ultimately causing constitutional symptoms analogous to those of pyæmia when otherwise derived.

The urine being obviously either the source or the vehicle of the morbific matter, it remains to inquire whence and in what circumstances it becomes thus contaminated. To help in answering these questions the author has collected the particulars of 69 cases from the *post-mortem* books of St. George's Hospital. The disorder was traced to mechanical obstacles to the escape of urine (stricture or enlarged prostate) in 31 cases; to paralysis of the bladder in 17; to stone in the bladder or operation for its removal in 15; to cystitis from other causes in 5; and in 1 to a renal calculus complicated with enlargement of the prostate. Looking at the urine as directly connected with the origin of the disease, it appears that three conditions usually concur—retention, ammoniacal decomposition, and admixture with the products of mucous inflammation. Of these, ammoniacal decomposition appears to be essential, or at least to be constantly present. The urine is generally fetid and more or less mixed with vesical products, pus, mucus, and blood. The ammoniacal change, although possibly arising independently of mucous inflammation, produces it so constantly that the origin of the disease is always thus complicated. The clinical antecedents to this condition are fundamentally of two kinds—those which begin with retention, and those which begin with cystitis; both in the end producing an ammoniacal and putrescent state of urine. Mechanical obstacles and loss of expulsive power, belonging to the first and larger class, occasion the retention and subsequent decomposition of urine, and its consequent admixture with the products of mucous inflammation. Stone and other vesical irritants, belonging to the second class, begin by causing morbid vesical discharges, which render the urine prone to decomposition, and ultimately induce in it a putrescent condition, not altogether dissimilar to that which springs from retention. The rarity of the renal disease as a consequence of stone in the kidney is probably to be explained by the less putrefactive tendency of the discharges from the pelvic membrane, or of the urine in that cavity.

In cases otherwise so tending, catheterisation, lithotrity, or some such instrumental proceeding, seems sometimes to act as the immediate instigator of the morbid process, as is witnessed by the common phrase which stigmatises the disease as the "surgical kidney." The disorder, however, may arise independently of any surgical invention, and would perhaps be better distinguished by the term *uriseptic*, which would declare its general clinical relations more comprehensively.

Having regard to recent researches which have associated the lower kinds of organic life with pyæmia, it is worth noting that the condition of urine which causes the disease now in question is one in which vibriones and bacteria abound. From this, however, no inference as to the nature of the virus can be safely drawn, except that it is associated with decomposition.

Passing to the symptoms of the disease, they have a general resemblance to those of pyæmia, being those of blood-poisoning rather than of renal inflammation. Unlike what happens with pyæmia, organs other than the kidney appear seldom to share in the suppurative process. The complaint usually ends fatally within three weeks of the first symptom, though there is evidence that recovery sometimes occurs. Perinephritic suppuration is an occasional result.

In treatment our efforts must be directed chiefly to prevention, to which end, beyond cautious surgery, measures of two kinds suggest themselves. First, the preservation or restoration of the natural acidity of the urine, a matter of most difficulty where it is most needed; secondly, as a suggestion as yet unwarranted by experience, the introduction of antiseptics by injection into the bladder.

To sum up: the form of renal suppuration which may be termed uriseptic has its origin in ammoniacal and putrid urine, poison from which is conveyed by the veins into the substance of the kidney, and then infects the system, causing symptoms in some respects resembling those of pyæmia. As this form disease is little obedient to curative medicine, though necessarily fatal, our efforts must be directed towards correction of the state of urine from which it springs.

◆

DUBLIN OBSTETRICAL SOCIETY.

At the fifth meeting of the Dublin Obstetrical Society on Saturday, March 8th, the Senior Vice-President in Chair, the following communications were made to Society:—

Dr. **Morgan**, "Specific Inflammation (Dactylitis) of Hands and Feet in Children."

Dr. **Kidd**, "A Case of Vesico-Vaginal Fistula."

A lengthened report of the proceedings will appear in next issue.

◆

DUBLIN PATHOLOGICAL SOCIETY.

At the meeting of the Society on Saturday, March Dr. **Edward Hamilton** said he was indebted to Bookey for the privilege of bringing the specimen which had before them under the notice of the Society. It been taken from the body of a female, æt. 60, received at Steeven's Hospital School. On opening the abdomen a tumour was found to occupy the right lumbar region. was so large as to displace the liver upwards, and it also placed the cæcum. On examination, it presented the appearance of a large mass of fat in connection with the right They had before them the specimen almost in its shape. The pelvis of the kidney was completely upon by this enlargement, and the structure of the kidney itself was undergoing a certain degree of fatty degeneration On making a section this adipose tissue appeared to be an aggerated condition of the adipose capsule. The bladder perfectly healthy and contrary to what he might have pected; there was no supplementary enlargement of the opposite kidney, which was of the ordinary size. The tumour weighed 1 lb. 6 oz. There was no remarkable development of fatty tissue in other parts of the body. Calcareous concretion existed in the pelvis of the kidney and was moulded to it. It was analysed by Dr. Bell and found to consist of urates with some phosphates. The specimen was of interest with respect to the statement made by Rokitanski, that in certain cases, especially of persons advanced in life, there might be an enormous development of ordinary fatty capsule, but it was very likely to occur where the pelvis of the kidney had been subjected to prolonged irritation. If his (Rokitansky's) statement be correct they had before them a remarkable example of the irritation caused by a renal calculus giving rise to hypertrophy of the adipose capsule.

Dr. A. W. **Foot** exhibited

THE LUNGS, HEART, KIDNEYS, AND SMALL INTESTINES OF GIRL, ÆT. 10, WHO HAD BEEN EXPOSED TO THE POISON OF SCARLATINA.

She had had suppression of urine more or less for two days;

desquamation was observed upon the hands, and the solitary glands of the entire tract of the small intestines exhibited the granular enlargement to which, in the last volume of the "Medico-Chirurgical Transactions," Dr. Harley has drawn attention as very characteristic of the pathological effects of scarlatina. She was brought to the Meath Hospital almost moribund, with effusion into the chest and consolidation of the lung. During the six days which she survived her temperature was subnormal, with the exception of the day of her death. The partial patency of her foramen ovale may have had something to do with this phenomenon. Fibrinous coagula in the right auricle and in the left ventricle had undergone central softening, and become converted into globular cysts containg a puriform liquid. The mucous membrane of the small intestines, from the orifice of the common duct to the ilio-cæcal valve, appeared as if strewn with grains of sago, the solitary glands presenting themselves as visible and palpable whitish firm beads from the size of pin's heads to that of hempseed; this condition is termed by the French pathologists "psorenterie;" by Rokitanski it is described as the "non-typhous intumescence of the follicles;" and by others as granulations of the intestinal mucous membrane. There was no ulceration of any of the enlarged glands; the agminated glands were not affected; 150 of these granular beads could be counted on any two inches of the ileum; they were found on the valvulæ conniventes as well as on the intervening spaces; held against the light on a plate-glass they were seen as black spots; microscopic examination of the contents of one of them showed only molecular granules. He considered the immediate cause of death to be lobular or catarrhal pneumonia and pleural effusion, but that the child was the subject of latent scarlatina.

At the meeting on Saturday, March 8th, 1873, Dr. KENNEDY, in the Chair.

TUBERCULAR MENINGITIS, ACUTE TUBERCULOSIS, DISEASED CONDITION OF SOLITARY GLANDS OF INTESTINE.

Dr. NIXON said the specimens which he exhibited were taken from the body of a boy, æt. 14 years, admitted under his care into the Mater Misericordiæ Hospital on the 14th ult. The particulars learnt regarding the case were briefly as follows: For a period of twelve months he had been subject to occasional attacks of headache. During five weeks prior to admission he complained of loss of appetite, and his manner was noticed to be dull and listless. When he (Dr. Nixon) first saw him his pulse was feeble but infrequent. There was increased heat of skin. The tongue was covered with a white creamy fur. The boy appeared somewhat stupid, and he complained of a slight cough. The lungs were carefully examined, but beyond a slight inequality of breathing on left supra spinous region as compared with same region on opposite side nothing abnormal could be detected. There was no diarrhœa, no inflation of abdomen or abdominal tenderness. Two days after admission the stomach became very irritable. The vomited matters were green in colour and were expelled without effort, severe shooting pains in the head were complained of. The boy became more stupid, the coating on the tongue changed to a dirty-brown colour. The urine was examined. It was acid in reaction, its sp. gr. 1·012, free from albumen and tube casts. It contained a large quantity of phosphates, numerous crystals of the triple phosphate being visible on microscopic examination of a recent specimen. The symptoms complained of were evidently cerebral in their origin, and the case was looked upon as one of tubercular meningitis.

On the 20th, after having blistered the head, the vomiting ceased. The stage of depression set in. The pulse was reduced to fifty-five beats per minute. The temperature in the axilla varied from 94° to 97° F. fluctuating between morning and evening. The heat of the lower extremities had to be maintained artificially. The cerebral stain on the skin was well marked. On the 22nd a murmur developed itself for the first time in the heart. It was post-systolic, and heard most distinctly at the apex. On the 23rd ult. there was ptosis of left eyelid, both pupils were dilated, the left one especially so. The right arm and leg seemed to have lost all motor power, the left arm and leg were flexed and rigid. The respiration was sighing but regular. The following day the temperature rose to 102° F., the pulse quickened, being 120 beats per minute. The boy was in a state of complete stupor. He was attacked by convulsions, they were ushered in by a faint scream and continued with intervals of cessation for twenty-four hours, when the breathing became very rapid, and the pulse quick and feeble. The boy gradually sunk and died about two o'clock on the morning of the 28th. On removing the calvarium the vessels of the dura mater and the sinuses were found distended with black fluid blood. The vessels of the cerebrum were congested. The surfaces of the hemispheres on each side of the longitudinal fissure were coated with headed granular lymph. The arachnoid in several places was thickened and opaque. At the base of the brain, corresponding to the great anterior subarachnoid space, he found a large deposition of lymph involving to a great extent the origin of left third nerve. There was also an effusion of lymph on the surface of the pons varolii. The arachnoid covering lateral subarachnoid spaces was opaque. The lateral ventricles were distended with serous fluid, slightly turbid from the deposition in it of small shreds of lymph. The posterior cornua were considerably enlarged. There was no marked softening of the brain substance. The heart presented no evidences of disease. Its valves were normal. The right cavities were filled with black clotted blood, and portions of dark grumous clots were adherent to the muscular fibres of the ventricle and auricular appendix. He was unable to account for the production of the murmur which had existed, except that it might be caused by the progressive debility of the muscular structure of the heart, which he thought arose in the course of the disease. The lungs presented an example of acute miliary tuberculosis. The liver and spleen also showed evidences of tubercular deposition, and small nodules of tubercle were found in the corticle substance of both kidneys.

A special point of interest in the case was the condition found in the lower portion of the small intestine. The mucous membrane covering the lower third of the ileum, presented a number of little projections scattered irregularly over its surface, and giving the appearance of little grains of sago or small shot being deposited beneath the mucous membrane; moreover, seven or eight of the solitary glands lying near the ilio-cæcal valve were greatly enlarged, the seat of deposition and ulceration. The deposed matter was white and granular in appearance, and presented the same microscopic characters as the heated lymph found on the surface of the brain. The intestine was in the condition described as "psorenterie," a morbid state, associated by Dr. Harley with the pathology of Scarlatina in his paper on the relation of that disease to enteric fever. A recent specimen of the same disease occurring in scarlatina was exhibited to the society at its last meeting by Dr. Foot. There was, however, nothing in the present case to connect the diseased condition with scarlatina. The boy had been a year complaining of occasional headaches, but enjoyed otherwise tolerably good health. There was no history of sore throat or eruption; no glandular enlargements of the neck; no diseased condition of the throat, neither albuminuria nor desquamation of the skin. He (Dr. Nixon) thought the diseased condition of the intestine might, in the present instance, be looked upon as simply the result of the tubercular state of the system affecting the mucous membrane of the intestine, leading to infarction of the solitary glands, and producing ultimately their ulceration.

RUPTURE OF THE AORTA.

DR. YEO showed the heart and aorta of a blacksmith, æt. 44, who died suddenly. He had been a hard liver, had syphilis, and for the last two years had suffered from dyspnœa, pain in the precordial region, occasional hæmoptysis, and œdema of the lower extremities. He had a double aortic bruit, loud bronchial *râles*, and albuminuria. While in hospital a third bruit was developed over the base of the heart, at the end of the second sound, the other two remaining distinct. He died while sitting up in bed. The *post-mortem* examination showed the lungs to be œdematous. The pericardium contained about one and a half pints of soft, dark clots, and one pint of dark fluid. The anterior surface of the right auricle and the aorta were ecchymosed, and on the anterior surface of the latter was a transverse slit three-quarters of an inch long. The auricles were small, the ventricles were dilated, the left hypertrophied. The aortic semilunar valves were enormously large—one measuring one and three-quarters of an inch in length—but they sufficiently closed the immense aortic orifice. The rupture of the internal and middle coats extended for two and a half inches transversely across the anterior aspect of the greatly dilated aorta, immediately above the attachments of the valves. The coats of the vessel were healthy. Dr. Yeo considered the case interesting—1st. From the three distinct bruits at the base of the heart; one of the two diastolic being caused by the blood rushing back to the dilated aorta, and the other by the rupture, allowing one attachment of the valves to yield, and thus permitting regurgitation; 2nd.

From the great amount of dilatation without any corresponding disease of the coats of the vessel; 3rd. From the rupture of the vessel, which he considered was caused by the drag of the enlarged valves on the internal and middle coat during the contraction of the elastic and distended aorta.

COMPLETE TRANSPOSITION OF VISCERA.

DR. NIXON presented to the Society a case of complete transposition of the viscera. The morbid specimens were taken from the body of a boy, aged about 15 years, admitted into the Mater Misericordiæ Hospital on Friday evening last. He was seen by the resident pupil, but died a few hours after admission. No history of the case was obtained. The *post-mortem* examination was made by his colleague, Dr. Browne. The cause of death was recent double pleurisy with effusion. The alteration in the position of the viscera was observed. The apex of the heart pointed downward forwards, and to the right side. The systemic portion was placed to the right, the pulmonic portion to the left side. The order of parts at the base, travelling from left to right, were superior cava, aorta, and pulmonary artery. The arch of the aorta at first passed upwards and forwards, and to the left, then transversely backwards from left to right, crossing over the upper part of the root of right lung. The aorta then passed down the posterior mediastinum, lying to right side of œsophagus. The branches of the arch were given off in the following order, from left to right, and from before backwards, arteria innominata, right carotid, and right subclavian. The arteria innominata passed upwards and forwards to left sterno-clavicular articulation, where it divided into left carotid and left subclavian arteries. The right branch of the pulmonary artery was shorter than the left. It gave off the ductus arteriosus, and entered the lung above its corresponding bronchus. The order of parts forming root of right lung from above downwards, being artery, bronchus vein, that of left being bronchus, artery vein.

The superior cava passed upwards over front of root of left lung, and was joined immediately above left bronchus by the vena azygos major, which passed up left side of posterior mediastinum. The left bronchus was short, wide, and transverse in direction, the right, long, narrow, and oblique. At the bifurcation of the trachea, the septum was seen to lie on the right side of the medial line. The left lung was divided into three lobes, the right into two. The right pneumogastric nerve passed downwards over the arch of the aorta, giving off at right side of ductus arteriosus the right recurrent laryngeal. The left recurrent nerve arose from the pneumogastric, where it crossed the left subclavian artery. Both nerves then took the usual course upwards between the trachea and œsophagus. Both pneumogastrics passed downwards to the back part of roots of lungs. The right one then descended on the anterior surface of the œsophagus and supplied anterior surface of stomach. The left supplied posterior surfaces of œsophagus and stomach. The liver occupied the left hypochondriac region, its great right lobe being directed to the left. The vessels passing up through the lesser omentum were placed as follows:— Hepatic duct to the left, hepatic artery to the right, vena porta behind and between both. The cardiac end of the stomach was directed to the right side, both it and the spleen occupying the right hypochondriac region. The convexity of the duodenum was directed to the left side, lying to the left of the vertebral. In its concavity was lodged the head of the pancreas, the tail of which passed from left to right, and touched the lower extremity of the spleen. The cæcum and its vermiform appendix occupied the left iliac region, the ascending colon lay in the left lumbar region, the descending colon in the right. The sigmoid flexure of the colon was placed in the right iliac fossa. The abdominal aorta lay on the right side of the spine. The left renal artery arose higher up than the right, but it took an oblique course downwards to the left kidney, which was placed lower down than the right one. The right renal artery had in front of it the right renal vein, whilst the left was covered by the right and left renal veins and the inferior cava. The right spermatic vein opened at right angles into right renal vein, the left terminated obliquely in inferior cava. He presumed the right testicle descended lower down than the left, but he had not measured the spermatic cords. The left common iliac artery was longer than the right, and posterior to it lay the right and left common iliac veins and commencement of the inferior cava. The left iliac vein first lay internal to the artery, then crossed beneath it to its left side. The inferior vena cava passed upwards on the spine, lying to left side of aorta, pierced the diaphragm on the left side of mesial line and opened into right auricle.

Dr. NIXON said that this was the third case of the same nature exhibited to the Pathological Society of Dublin. The first case was shown by Dr. Mayne, the second by Professor Smith. He regretted the latter one had not been recorded, as an explanation of the cause of the transposition had been offered.

Professor SMITH believes that the change of position depends on an arrest of the development of the heart. That this organ in its earliest formation, undergoes a movement of torsion, which if arrested, results in an altered position of the cavities of the heart, and of its afferent and efferent vessels, and that this departure from the usual mode of development, is the primary cause of the transposition of the other viscera.

◆

HOSPITAL OUT-PATIENTS REFORM ASSOCIATION.

A MEETING of the Association was held in the Medical Society's Rooms on Thursday evening, March 5th. Dr. A. Meadows in the chair.

The reforms adopted by the meeting were as follows:—

1st. That each out-patient at every visit to a hospital shall be seen personally by one of the Medical or Surgical staff, and that no unqualified student be permitted to prescribe for out-patients.

2nd. That a lay officer attached to each hospital be instructed to see that the charity is not abused by persons being admitted as out-patients, who are well able to pay the usual fees of practitioners, or to obtain Medical attendance by provident dispensaries or otherwise.

3rd. That patients shall no longer be tempted to crowd to hospitals by the offer of medicine gratuitously. We are therefore of opinion that no medicines should be supplied to out-patients at hospitals, except in the case of in-patients who are made out-patients for a time; but that advice and prescriptions be alone given.

Dr. MEADOWS said that his only right to be President was that for 15 years he had been acquainted with the working of out-patients in hospitals. What was but a floating idea is now becoming fixed. In several of the hospitals the question of out-patient abuse is being taken notice of. The present system is a gross injury to the Medical man, both general practitioner and consultant. The degrading influence on the laity is also very great. In all large towns the abuses are quite as great as in London. The *Manchester Guardian* has lately taken up this question. There are in that city 23 Medical charities, and 111,000 persons get relief from these charities gratuitously. In 1836 the proportion of persons receiving relief was 1 in 8½ of the population; it is now 1 in 4 of the population. Four out of five of these are totally unworthy of relief. When hospitals were founded there were but few out-patients. "Hospital Sunday" has some dangerous features, if the present out-patient system continues, and will require to be jealously watched.

Mr. HOLMES moved Resolution 1. It seemed to him that the proposition was self-evident. He desired that the out-patient system should be utilized by weeding out all trivial and unimportant ones. We ought not to allow out-patients to pay, that would be a bad way. A good number of out-patients come to get an opinion, who have been attending other practitioners. It is a great abuse to have numbers of trivial cases attended by eminent men. It is a gross and monstrous abuse to allow poor patients to be seen as now is done by students. It is impossible to teach any student anything in the short time allotted to each patient at present.

Dr. FORD ANDERSON endorsed heartily all that fell from Mr. Holmes, and regretted much the valuable time he had lost as a student in so rapidly prescribing for hosts of cases. Patients are too often injured gravely by the mistakes of students. The object of this association is to teach the public such facts as these.

Dr. HEYWOOD SMITH observed that students should see trivial cases as well as difficult ones, and was inclined to desire some small change being made in the wording of Resolution 1.

Dr. ROGERS said that no unqualified person is admitted to prescribe for any pauper in Poor-law districts. Why should this any longer be the case in hospitals?

Dr. GLOVER said the remedy appeared to lie more in enlargement of the staffs of the various hospitals, than in lowering the number of cases seen. He desired to add as a rider to this first resolution that the number of the staffs of the hospitals should be increased.

Mr. **Benson Baker** said that the out-patients of hospitals were of three classes; those who can afford to pay a doctor, those who should support provident dispensaries, and thirdly, those who should go to the poor-law dispensaries. Hence the expediency of the resolution was evident.

Dr. **Chapman** thought Dr. Glover's amendment of such importance that he would support it. His experience at his own hospital suggested the advantage of enlarging the staff.

Dr. **Mason** did not agree with the idea of augmenting hospital staffs. Influence should be brought to bear on the present hospital staff. General practitioners might do much for themselves. He had for some years allowed poor patients to consult him for 1s. 6d. or 2s. in the evening. Some plan must be shadowed forth for the working classes to get relief at small cost. The provident dispensaries were not enough. The Hospital Sunday may do much good if only watched.

The resolution was carried, and the amendment lost.

Dr. **Steward** moved Resolution 2. A striking feature, he said, of the present day, is the wholesome criticism of all our institutions. When he came to London he found that Chalmers was wrong when he said that Medical charities were the only ones that could not be abused. The public believe that there is always some *rat* beneath all treatment of poor patients at hospitals. The hospitals have a relation to the poor. Charity which is blind is no charity. It makes the poor thoroughly mercenary. It benefits only two classes—the gin-shop keeper and the lodging-house keepers. The hospital governors have a duty to the public they are bound to discharge, for they pauperise so many at present by indiscriminate relief.

Dr. **C. Drysdale** seconded this resolution. He had become convinced of the importance of changing the ordinary dispensaries of London into provident dispensaries, and had been able to carry a resolution to that effect a day or two ago at the Farringdon General Dispensary. The only difficulty lay in the third class of patients alluded to by Mr. B. Baker, for, unfortunately, all patients at present of poor-law dispensaries were made paupers and disenfranchised. If an amendment could be made in Mr. Hardy's Act preventing this, the question would be simplified.

Dr. **Rogers**, some years ago, found that £118,000 a year was spent by the city of London on Medical charity, and this accounted, he thought, for the number of poor in that union. Pauper Medical relief at present is disenfranchising, because Government wishes to keep down the charges on Medical men. So long as there is so much gratuitous advice from hospitals the poor-law system would work ill.

Mr. **Holmes** said that only 20 patients are admitted as new cases at St. George's Hospital to each practitioner each day. There are not many abuses in St. George's now-a-days, since the numbers of out-patients were so much diminished.

Mr. **Benson Baker** moved the third resolution. It is, he said, reported that many patients use the cod-oil for lamps. The Western General Dispensary is most pauperising in its effects in Marylebone.

Dr. **Staines** seconded the resolution.

Mr. **Holmes** did not wish to oppose the third resolution; but thought that a certain number of in-patients might be treated as out-patients after leaving.

Dr. **Heywood Smith** agreed with Mr. Holmes.

Dr. **O'Connor** also thought this third resolution was rather hurriedly framed.

Dr. **Holmes** added a rider to the third resolution to the effect that in-patients might be seen as out-patients afterwards for a short time and receive medicine.

This rider was added, and the resolution was carried.

Mr. **Streatfield** proposed the following names as members of the Council of the Association:—President: Dr. Meadows. Vice-President: Dr. J. F. Staines. Treasurer: Dr. Walter Smith, 18 William Street, Regent's Park, N.W. Hon. Secretaries: Dr. J. Ford Anderson, 28 Buckland Crescent, N.W.; Mr. H. Nelson Hardy, 21 Fitzroy Square, W. Committee: Dr. Leslie; Dr. A. Grant, Honduras Terrace, Commercial Road, E.; Dr. H. Hanks, 146 Mile End Road, E.; Mr. R. H. S. Carpenter, Union Place, Commercial Road, E.; Dr. Davison, 7 Oxford Terrace, Holloway, N.; Mr. J. E. Richards, 12 Caswell Grove, Hackney; Mr. Benson Baker, 42 Grove Road; Dr. Thomas, 39 Nottingham Place; Dr. Anstie; Dr. C. Drysdale, 99 Southampton Row; Dr. Tilbury Fox.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 12, 1873.

THE NEW ARMY MEDICAL WARRANT.

The long-expected Medical Warrant has at last been issued. The ranks of Medical officers are changed, but the rates of pay remain unaltered. The designation of the administrative grades will henceforward be surgeon-general and deputy surgeon-general; of the executive, surgeon-major and surgeon; their several rates of pay being as follows:—

	Daily. £	s.	d.	Charge pay.
SURGEON-GENERAL	2	0	0	The Principal Medical Officer of an Army in the Field, consisting of 10,000 men and upwards, £1 daily; of 5,000 men and upwards, 15s. daily; of less than 5,000, 10s. daily. Or the Principal Medical Officer of a Colony where the number of commissioned officers and enlisted men is 1,500 and upwards, 5s. daily.
After 25 years' service ...	2	5	0	
" 30 " ...	2	7	0	
" 35 " ...	2	10	0	
DEPUTY SURGEON-GENERAL...	1	10	0	
After 25 years' service ...	1	12	0	
" 30 " ...	1	15	0	
" 35 " ...	1	17	0	
SURGEON-MAJOR	0	17	6	
After 15 years' service ...	1	0	0	
" 20 " ...	1	4	0	
" 25 " ...	1	7	0	
SURGEON, on appointment ...	0	10	0	
After 5 years' service ...	0	12	0	
" 10 " ...	0	15	0	

Their relative rank remains unchanged, except as regards the grade of surgeon. A surgeon, now that the "assistant" has been abolished, shall rank as lieutenant, according to the date of his commission; and, after six years' full-pay service, as captain, according to the date of the completion of such service.

The relative rank of these officers shall regulate choice of quarters, rates of lodging money, servants, fuel, and light, or allowances in their stead, detention and prize-money, as well as allowances granted on account of wounds or injuries received in action, and pensions and allowances to widows and families; except that in the case of Medical officers attached to regiments their choice of quarters shall be according to their regimental seniority.

Forage shall be granted to officers of the Army Medical Department for such number of horses as are necessarily kept by them for duty, and in this paragraph we think we see the germs of some little difficulty to the Medical officers in regard to the actual numbers of horses they may severally draw forage for.

We regret to observe that no provision for accelerating promotion appears in the Warrant; the tenure of office in the highest rank remains unlimited as it has been since the famous Warrant of 1858, and the rates of half-pay granted to all below that rank are unlikely to prove attractive. The following are the paragraphs bearing upon these points, viz.:—

"Medical officers shall have a right to retire on half-pay after twenty years' service. Medical officers of the rank of surgeon-major or surgeon shall be placed on the retired list at the age of fifty-five, and all surgeons-general and deputy surgeons-general at the age of sixty-five years; unless in any special case it would be for the good of our service that the officer shall continue in employment.

"Our Secretary of State may, when he shall deem it fit, employ Medical officers on the half-pay list in special situations at such daily rates of pay, in addition to half-pay, as he shall from time to time determine; but such officers shall vacate their appointments on attaining the age of sixty-five years.

"A Medical officer who, having voluntarily resigned his commission, has subsequently been permitted to re-enter the department, shall not, except under very special circumstances, to be approved by our Secretary of State, be allowed to reckon his former service."

A Medical officer placed on half-pay by reduction of establishment, or on the report of a Medical Board in consequence of wounds or ill-health, caused in and by the discharge of his duties, or on account of age (under Article 20), will be entitled to half-pay in accordance with the following scale:—

	Daily.		
	£	s.	d.
Surgeon-General, after 30 years' service	1	17	6
,, ,, 25 ,, ...	1	13	6
,, ,, 20 ,, ...	1	10	0
Deputy Surgeon-General, after 30 years' service...	1	5	6
,, ,, 25 ,, ...	1	2	6
,, ,, 20 ,, ...	1	1	0
Surgeon-Major, after 25 years' service	1	0	0
,, ,, 20 ,, ...	0	16	6
,, ,, 15 ,, ...	0	13	6
,, ,, 10 ,, ...	0	11	6
Surgeon, after 10 years' service	0	10	0
,, ,, 5 ,, ...	0	8	0
,, under 5 ,, ...	0	6	0

Here follows a paragraph, however, which considerably restricts the rates allowed to Medical officers who have looked forward to retirement on £1 per day after twenty years' service, as many of them have done, namely:—

"The rate of half-pay awarded to officers retiring for their own convenience, after twenty years' service on full pay, under Article 20, shall not exceed one-half of their full pay at the time of retirement."

In other words, a surgeon-major can only claim the right to retire after twenty years' service upon the munificent allowance of 12s. per day, that is a little more than the price of a quarter of a ton of coals at the present "quotation" of the latter. There are some special regulations as to Medical officers engaging for service on the West Coast of Africa, viz.:—

"Service of Medical officers upon the West Coast of Africa shall be voluntary, except for those who enter the department especially for African service.

"Each year or portion of a year shall be allowed to reckon double towards retirement, but not towards increased pay, provided that the officer shall serve at least twelve months on the West Coast of Africa.

"For each year's service on the Coast a Medical officer shall be entitled to a year's leave at home, and for every additional period beyond a year he shall have an equivalent extension of leave.

"Officers who may enter the Army Medical Department expressly for service on the West Coast of Africa, and those who may volunteer for that service from the General Department, after the date of this Warrant, shall receive double pay while actually serving on the Coast.

"Officers who enter the department expressly for service on the West Coast of Africa shall pass the same examination as other Medical officers, but they may be admitted at a later age. They will be required to complete three years' actual service on the coast, after which they shall be eligible for general service. If it shall be certified by a Medical Board that any such officer is unfit for further duty on the West Coast of Africa he may be employed elsewhere, notwithstanding that he may have served for less than three years on the coast."

A careful perusal of the Warrant leads us to the conclusion that it will fail to satisfy the Medical officers.

HOSPITAL OUT-PATIENT REFORM.

It is questionable if anything fresh can be said on the subject of hospital abuse; yet the matter is one on which it is better to continue "saying the same sad thing" than to allow it to rest. We are glad to see the agitation now going on in many quarters against a system in every way so objectionable. Some pamphlets (*a*) published recently treating on the question are singularly happy in their statistics and illustrations, exposing the mean wicked farce which is daily growing greater, not only in London, but in all great towns, and is really doing much more injury to the public than to the Profession.

Certain of the facts would, we think, startle not a little some readers unacquainted with the working of our hospital out-patient systems; for instance, that at one of our largest and most celebrated institutions "120 patients were seen and dismissed by one Medical officer in an hour and ten minutes, or at the rate of thirty-five seconds each." Thirty-five seconds each to examine and prescribe for patients, many of them of course seriously ill, what would a dyspeptic duchess say to the same treatment? Now, Medical advice is either worth something or nothing, if half an hour be not long for the wealthy patient, it is pretty clear that those unfortunates who each received their thirty-five seconds would have been just as well without any doctor at all, and would not have lost their self-respect by coming to beg.

The only hope for out-patient reform is in the possible return of common sense to the public, and their perception of that which is to us so obnoxious, namely, "that which is obtained for nothing is usually worth just exactly what it costs." Possibly the hospital doctor would, on quitting the hospital, drive to some ailing grandee and pass at least half-an-hour in her luxurious drawing-room, and if he arrive late will heartily wish he had given his hospital patients fifteen instead of thirty seconds each. The answer to this by the public often is—but this doctor is guilty of a breach of contract, he undertook to attend to those patients when he took his position; no doubt he

---

(*a*) "Hospital Out-Patient Reform." By Nelson Hardy, F.R.C.S. 'Letter to the Governors and other Subscribers to St. George's Hospital.' By One of Their Number. "Letters to the *Times* and *Lancet* on Famine Fever and Public Charities." By Sir Charles Trevelyan, K.C.B.

did, but if he acted like a perfect individual he would do so, but alas, he belongs to our poor human nature, he thinks of those he has to support at home, and he "gets through" impatiently, and runs away quickly from those who pay him nothing, and to whom he does little or no good, to visit those by whom he makes his living and whom having time he can hope to relieve or cure.

The only remedy we can see is to bring home to the public mind the conviction that it is not worth while to go to a hospital as it is at present, that if they desire the privilege of waiting some hours in a close, unhealthy, and possibly infectious atmosphere, with the prospect of a half minute's interview with a tired, hurried, and possibly irritable doctor at the end, in fact, for the advantage of being looked on as beggars (and being such) and receiving corresponding treatment, they can obtain this blessing gratis; but that if they are ill and are seeking the restoration of health, they must apply elsewhere, and in other form than as mendicants, and receive Medical attention without loss of self-respect, that by paying for what they receive they may get something worth having. It is a poor gift to give for nothing that which must usually be useless and sometimes pernicious.

AUTHORS AND EDITORS.

Last Friday a barrister was charged at the Guildhall Police Court with having stolen a book from the Library of the Inner Temple. During the examination a second-hand bookseller was called, whose evidence disclosed a very reprehensible practice—one which cannot have too great publicity. This witness stated that "he bought the book from the defendant knowing him to be a barrister and an editor; *he supposed it to be a presentation copy sent for review.*" To authors who have not been amongst the favoured few to gain a notice of their works, this will explain much, and at the same time the thought will not afford them much consolation, that their labours have gone to enrich the pockets of those whose duty is not unnaturally supposed to be that of criticism, and not barterers of other people's brains and money. We have heard of one editor who makes £600 annually by the sale of books sent for review, and we doubt not that there are higher figures reached even than this. As conductors of an organ of the press, this is a sorry confession to make, but we hold it as incumbent upon all honest journalists to frankly avow their disapprobation of a practice which is nothing short of robbery. From the evidence given one would imagine that the practice is more common than is generally supposed. Of course we do not contend that every book and pamphlet sent should of necessity be reviewed; and, even after criticisms have been given, it may be an open question whether the sale of the works may not be strictly in accordance with literary probity; but what we do complain of is that, in the majority of instances, not one in every twenty books sent for review is even opened, so that the critics are unable to pass an opinion one way or the other, and valuable and useless brain-work alike is quietly consigned to the shelves of a second-hand bookseller, and a proportionate, or, as it would seem in the present instance, a disproportionate, sum is coolly pocketed by men who sink a noble profession to one of the most detestable depths. We are aware that we shall be accused by our brethren of the press of undue severity, and by some reminded that half of the works sent never reach them at all; we admit and deplore this, but the whole system is bad, and the sooner it is altered the better will the literary world and the public be for the change.

Notes on Current Topics.

Vaccination from the Heifer.

Dr. E. A. Carleton, of Boston, U.S., gave a lecture on vaccination, on Thursday, March 6th, to the students of the "Ladies Obstetrical College of London." In the course of the lecture the lady M.D. referred to the fact that in Boston, Mass., the practice of heifer vaccination has for some time past been carried out by Dr. H. A. Martin, who could boast recently of having made 500,000 vaccinations from the heifer with perfect success, and never followed by any grave results. The young cows are taken at the age of from six weeks to four months old; and 100 such heifers are kept in stock. Two new heifers are inoculated daily, and lymph is distributed to the different States of the Union from Boston, a dozen points being sent off for a dollar—or four shillings. Dr. Martin has vaccinated 9,000 persons with his own hands at home; and has bought an estate quite recently for the purpose of feeding a herd of cattle, in order to have always healthy heifers ready for inoculation. Dr. E. H. Carleton had herself used the lymph furnished by Dr. Martin on many cases, and with best effects. The enterprise and energy of Dr. Martin contrasted most favourably with that of the French Government, which had only made use of 60 heifers a year. At the close of the lecture Dr. C. Drysdale said that he heard from Mr. George Critchett that, in Brussels, Dr. Warlomont was in the habit of keeping up heifer vaccination in the Zoological Gardens, and distributing supplies, like Dr. Martin, of Boston, to the practitioners of Belgium.

Filaria Sanguinis Hominis.

In a recent number the *Indian Medical Gazette* drew attention to the remarkable and important discovery by Assistant-Surgeon T. R. Lewis, M.B., of a hæmatzoon inhabiting the human blood. Dr. Lewis has published a complete account of his observations in the Report of the Sanitary Commissioner with the Government of India. In March, 1870, Dr. Lewis discovered the existence of a nematoid worm in cases of chylous urine. Since then he has had from 15 to 20 similar cases under observation and has found the microscopic filariæ in question in the urine of every one of them. It was not, however, till July, 1872, that he ascertained the presence of the same nematoid in the human blood. The discovery was made accidentally, while examining the blood of a native suffering from diarrhœa in the Medical College Hospital. After satisfying himself that the worm now found in the blood was the same as he had previously found in the urine, Dr. Lewis endeavoured to follow up the history of the case, but the man had meantime disappeared, and could not be traced or found. Other cases of chyluria, however, soon presented themselves, and in all of them he was able to detect the nematoid not only in the urine but in the blood; nay—strange to say—the very man in whose urine the worm was originally discovered, was found to be a printer in the office where Dr. Lewis's paper was being typed, and actually engaged in setting up the letter-press describing his own malady. His blood was forthwith searched, and the nematoid, which two and a half years previously had been found in his urine, was now found in his blood. The anatomy of the worm is most carefully described. It is an apparently structureless organism about 1-75″ long and 1-3,500″ broad. The number of these organisms inhabiting the blood is marvellous. As many as six worms have been found in a single specimen of blood; and Dr. Lewis estimates that the blood of an adult thus infested may contain some 140,000 individuals. It seems to inhabit every part of the circulating fluid, and has been found in the secretions of the kidneys and conjunctivæ. We transcribe his general conclusions :—

1. The microscopic filariæ are hitherto not identified with any known species, but may continue in the system for months or years without any marked evil consequences being observed, but which may, on the contrary, give rise to serious disease, and ultimately be the cause of death.

2. The phenomena, if any, are probably due to the mechanical interruption offered (by the accidental aggregation perhaps of hæmatozoa) to the flow of the nutritive fluids of the body in various channels, giving rise to the obstruction of the current within them, or to rupture of their extremely delicate walls, and thus causing the contents of the lacteals, lymphatics, or capillaries to escape into the most convenient excretory channel.

3. As a rule, the chylous condition of the urine is only one of the *symptoms* of this state of the circulation, although it appears to be the most characteristic symptom that we are at present aware of.

4. And lastly, it appears probable, that some of the hitherto inexplicable phenomena by which certain tropical diseases are characterised, may eventually be traced to the same or to an allied condition.

Glaucoma.

THERE still, unfortunately, remain several important questions for solution relative to the pathology of this disease, and the nature of the action of the great remedial discovery of V. Græffe. It is a subject for regret that national prejudices should be allowed to appear in the discussion of such questions. Dr. Fano can hardly keep his temper when writing about the "*errements regrettables propagés par l'école allemande*," and the "*therapeutique irrationelle*" to which oculists of that school have resorted. He expresses his opinion very decidedly against the mechanical theory of the manner in which iridectomy diminishes intra-ocular tension, and cures the disease. Having premised that the chances of the operation being successful in acute glaucoma, are greatly enhanced if there be free hæmorrhage into the anterior chamber, Dr. Fano asserts that this depletion is an energetic antiphlogistic; the blood thus drawn from the AA. ciliar. ant. supplying the iris, and communicating with the AA. ciliar. post. which go to the choroid, being a *direct* drain on the vascular system of the membranes of the affected eye. There is much to be said in favour of this view, especially as contrasted with others in vogue. But we do not think that some of the other opinions expressed by Dr. Fano (a) are equally well-founded. For example, he states, that without doubt, the optic papilla is not excavated in the majority of cases, and again that the iris is retracted, and not pushed forward. But still, one interested in this important subject will find Dr. Fano's letters will repay study.

Medical Inventors.

THE Medical Profession is one that opens a vast field of observation to its members; and in some instances on subjects apparently outside orthodox medicine, but really not so, as the study of nature in all her perfect laws is the province of our craft.

This week, a most rakish but beautiful schooner, of about 50 tons burden, leaves the Thames with the designer and owner, Dr. Collis Brown, for an experimental trial of her buoyant qualities at sea. Dr. Brown has taken his design from a fish of the Eastern waters, and so names his vessel "Ralifish," which, in Hindostanee interpreted into English, means black fish, and really such is the extraordinary-looking craft. The model of this vessel has attracted much notice, particularly at the Admiralty. The chief constructor there does not refuse to inspect a doctor's invention, especially as Dr. Brown engages to iron plate such a plan of vessel with metal three feet thick, having great buoyancy withal in a sea-way; so, perhaps, the great gunmakers may have to puzzle their brains for an efficient "iron pill" to penetrate such a vessel as a war steamer. We hope very soon to be able to report on the performance of the "Ralifish" at sea. Several gentlemen of scientific attainments will be on board, amongst whom is Dr. McGrigor Croft, of screw paddle-wheel and fish-tail celebrity. The "Ralifish" cost Dr. Brown at least two thousand pounds, and we wish his invention all success.

Electro-magnetic Paper.

IF the extent of the employment of electricity as a therapeutic agent can be measured by the number of apparatus brought before the public from time to time, it certainly must be very widely used. The *Aerzt. Literat. Bltt.* speaks in the highest terms of Royer's electro-magnetic paper in the treatment of rheumatism, neuralgia, gout, &c. In point of constancy, utility, and cheapness, it is stated to be unsurpassed.

Ice in the Treatment of Facial Neuralgia.

M. WENTERITZ reports a case of very intense facial neuralgia which resisted every mode of treatment, that finally yielded to the application of ice along the affected side of the face laid on at periods of five minutes. The pain disappeared in twelve hours, and after an interval, now of ten months, has not returned.

Dislocation of the Thumb.

A CASE of dislocation of the last phalanx of the thumb on the first with the very rare complication of the interposition of the flexor tendon between the articulating luxated surface is reported in the *France Médicale* of Feb. 17th, from the wards of M. Trelat in La Charité, Paris. The usual means were employed to reduce the dislocation without effect, Lüer's apparatus being used. An incision was made, as a last resource, on the anterior face of the thumb, in the direction of its long axis, and opposite the articulation in question. A blunt hook was introduced into the wound, and by means of it the flexor tendon was drawn first on one side and then in front, and then into the osteo-fibrous channel it normally lies in. The dislocation was reduced by this means, but suppurative osteitis of both the osseous extremities involved, followed. Instead of amputating, M. Trelat determined to save, if possible, the second phalanx, and succeeded, anchylosis of the joint becoming established, with a loss of about one centimetre in the length of the thumb. The result may be regarded as satisfactory, and a similar method of reduction should be tried before amputation is resorted to in the case of such an important finger.

(a) *La France Médicale*, No. 11, 1873.

Galvano-puncture in the Treatment of Aneurism.

Prof. Cotronei sums up the conditions which are most likely to lead to a successful employment of this means of treatment as follows :—

1.—The aneurism should not involve a main artery.
2.—The sac should be of small dimensions.
3.—The current of blood in the aneurism should be small and slow.
4.—The needles should be very steadily introduced to avoid causing any oscillation in the blood, which would act as a mechanical cause of inflammation.
5.—The artery should be compressed above and below the sac, both to retard the current of blood and to aid the formation of new clots (as well as prevent the disintegration of old ones).
6.—The needles should be introduced subcutaneously in such a way as to prevent the opening in the skin being opposite the opening in the sac, in order as far as possible to diminish the possibility of hæmorrhage.
7.—The needles when introduced into the sac should be directed so as to cross the outlet, and thus retard the current and prevent the escape of clots from the sac.
8.—The needles ought not be left longer than four or five days *in situ*.
9.—Cold applications should be employed simultaneously, as they help the formation of clots and diminish the chances of inflammation ensuing.

The author, while admitting that the employment of galvano-puncture has not been a success, and that Italy has had a good share of failures, is still of opinion that the operation modified and improved may be expected to lead to more satisfactory results than have hitherto been obtained.

Gonorrhœal Orchitis.

Prof. Richet gives a case at L'Hotel Dieu of specific epididymitis with effusion into the tunica vaginalis, treated by making an incision into the tunica vaginalis. Rest and keeping the parts raised with cold applications constantly used in the shape of spirit lotion. It is argued that a cure was effected in eight days, and that the patient was free from any danger of hydrocele or of occlusion of the ducts.

We doubt if this treatment will find favour with surgeons in this country.

Leucocythemia.

Prof. Mosler suggests that by the more frequent use of the microscope the connection of several scrofulous conditions, rickets, &c., in children with leucocythemia can be demonstrated very frequently. In 112 cases of leucocythemia he has seen but four which developed the symptoms after intermittent fever. He relates an interesting case of leucocythemia following a wound of the spleen.

Bichloride of Methylene as an Anæsthetic in Ophthalmic Operations.

In the **Medical Press** of Feb. 12th, Mr. Morgan, the house-surgeon of the Moorfields Hospital, in discussing the relative safety and efficacy of ether and other anæsthetics, says—In the bichloride of methylene we have an anæsthetic so very convenient in eye surgery that I should be unwilling to give it up in favour of any other until that had been proved by other people's experience to be decidedly safer than it is. I have had a comparatively large experience of this agent (about 2,800 cases) and have never been seriously alarmed by it, but I do not think it is absolutely safe, and would willingly adopt ether if it can be proved to be safer.

The London correspondent of the *Canada Med. and Surg. Journ.*, in its last issue, quotes the following opinion of bichloride of methylene, which he says he has received from Mr. Morgan himself :—

"On the bichloride being first administered to the patient, a sense of suffocation, compared to fainting, is felt, giving rise to struggling on the part of the patient, after which he falls into the same state as characteristic of chloroform."

This description certainly does not realise our idea of an anæsthetic "so convenient for ophthalmic operations that we should be unwilling to give it up in favour of any other." It seems to us that rapidity of action and elimination is the only good quality of the methylene anæsthetic, and that characteristic—however useful it may prove in the slap-dash surgery of big hospitals—is not to outweigh the perfect tranquillity which may be obtained in a very little less time by the undiluted ether vapour.

Venereal Diseases in the principal Armies of Europe.

The *Lyon Medical* quotes from the *Temps* some statistics of venereal diseases amongst the troops in the principal armies of Europe. In the French army during the year 1869 the proportion was 103 per 1,000 affections, and 60 per 1,000 sick from all causes; in Algeria, 113 per 1,000 affections, 87 per 1,000 sick; in Belgium, 100 per 1,000 affections; in Austria and Hungary, 63 per 1,000 affections; in Portugal, 95 per 1,000.

Marches of Armies.

Colonel Hamley gives, as a rule, as the fair length of a day's march, 15 miles for a division, 20 a long march, and over 20 a field march. Napoleon the 1st marched his army from the Channel to the Rhine in 1805, a distance of 400 miles, in 25 days, or 16 miles a day continuously. In 1870 the army of Prince Frederick Charles marched from Metz to the Loire, averaging 12½ miles a day. The 9th Corps averaged 13½ miles for the first 9 days, and then pushed on from Troyes to Fontainbleau, 76 miles in 4 days, or 19 miles a day. The same corps afterwards marched, on the 16th and 17th of December, 1870, nearly 50 miles in 36 hours on heavy roads in bad weather. The proportion of stragglers among the infantry varied from 12 per cent, to more, the average being under

4 per cent. An eye witness states, however, that some at least of the men seemed to have exhausted their nervous energy. It is added that cavalry and artillery ought to be prepared to march 25 miles a day for several days, and that Colonel Tod Brewer's battery of horse artillery marched in 1871 after the Autumn manœuvres, from Aldershot by Hounslow to Woolwich in one day, a distance of 44 to 46 miles, and appeared on parade the following day apparently not much the worse for it. In 1859, however, the French army of 100,000 strong marched only 4½ miles a day between the victory of Magenta and battle of Solferino.

Medical Handbook for Naval Officers.

Naval Officers, already reported the most highly-trained and scientific among those of the public services, have now—thanks to the energy of the Medical Director-General—been provided with easy lessons in yet another branch of knowledge, and it certainly is one of the most useful, if not the most ornamental, namely, that of treating diseases and injuries. The *Medical and Surgical Hand-Book*, lately issued for use in cases where the services of a Medical officer are not immediately available, is a model in its way, and reflects great credit upon whoever has been entrusted with the duty of compiling it. The remarks on the various subjects treated are concise and to the point, those subjects including such as refer to the hygienic condition of men and ships; the diseases to which sailors are most liable; the accidents and wounds most frequently met with among them; rules for restoring the apparently drowned, and some other matters useful to know.

We entirely agree with the author of this Handbook that "it is obviously the first duty of an officer in charge of the health of a number of men to ascertain what are the means most likely to insure its preservation." We would add that this duty is just as imperative upon officers in command of ships as upon their surgeons; and we would hope that the *brochure* now placed in the hands of the former will be the means of directing their attention to some of the methods by which this can most easily be affected, much to the advantage of the sailor in various ways. The instructions relative to sleeping accommodations on board small vessels are judicious, and the observations regarding the objectionable practice so often followed on board some naval ships of constantly washing decks, whatever be the state of the weather, will, it is hoped, be the means of drawing the attention of commanders to the fact that, in respect to it there may be too much of a good thing. The practice so common among sailors of eating portions of their salt pork in an uncooked state is pointed out as liable to be followed by the occurrence of tape worm, and that of some kind of prepared food, as sausages, shown to have unpleasant effects.

In the part devoted to the first treatment of accidents and wounds, illustrations are given showing the readiest means of applying such apparatus as may be necessary. The illustrations are excellent; but it seems to us that in the directions for putting up fractured limbs there is too much bandaging shown; that it would be better were there for example, special apparatus with buckles and straps, put on board small vessels for application in such cases, than such as the long splint, which at the best of times it is difficult to apply, and the bandages connected with them receive manipulation by a practised hand.

Abortive Treatment of Boils and Whitlow.

Dr. Simon de Forges (*Rev. de Therap.*) advises the topical use of camphorated spirits as an abortifacient in boils and whitlow. In the former case the boil is to be rubbed eight or ten times by the finger dipped in the alcohol. He asserts that it is rare that after this treatment a boil goes on further towards suppuration. In cases of whitlow he advises the patient to dip the finger for some ten minutes in camphorated spirits. This almost always gives great relief of the pain, and often cures the complaint.

Treatment of Cancrum Oris.

C. S. Kittredge, M.D., of Oakland, Cal. (the *Western Lancet*), late Assistant Physician at the Nursery and Child's Hospital, Randall's Island, N.Y., publishes 19 fatal cases of this formidable affection—which is a malignant form of ulcerative stomatitis—induced in children under five years of age, predisposed to tuberculosis. The duration of this disease is from six to sixteen days, running a most rapid course when commencing in the cheek or throat, but somewhat slower in its progress when commencing in the gums. The disease demands prompt and energetic attention. He commences with the chlorate of potassa, in from five to ten grain doses every four to six hours, and continues it during the whole progress of the disease. The mouth must be frequently washed with a weak solution of liquor sodæ chlorinatæ, ʒj. to water ℥xij.; and after mortification has commenced, a pledget of soft linen, wet in this solution, should be constantly kept between the sore and the adjacent tissue. Tonics and stimulants should be freely given on account of the great prostration, and iron with bark or quinine in as heavy doses as the child will bear, and strong beef-tea in place of solid food. Out of 67 cases of stomatitis treated during the year, there were 19 deaths, or 28 per cent. Of the fatal cases, 12 were males and 7 females. The average age was two years and eleven months. In 16 cases, the primary disease was rubeola. Fourteen autopsies were made, and in every case, tubercles were found in great abundance. In 13 cases the tubercles were in the lungs, and in the other, the mesentery was filled with miliary tubercles. He remarks in conclusion that cancrum oris has a close connection with tuberculosis; and believes that it can exist only in children of a tuberculous diathesis.

Cold Applications in Croup.

Dr. E. Tefft, Topeka, Kansas, recommends cold applications in croup. Communicating to the *Jour. Mat. Med.* his experience during a period of more than thirty years, during which time not a case in his practice has terminated fatally, he writes:—"I invariably use cold applications to chest and throat, and have had the satisfaction of seeing every case without a single exception recover. Even though I did not see my patients until in the last stage of the disease. I always applied ice to the throat and chest. This course of treatment gave prompt relief by detaching the false membranes. I occasionally administer expectorants as adjuvants, though the ice is my main reliance."

Napoleon's Case.

Last week Sir H. Thompson lectured at University College on the treatment of calculus. Seven cases were made the subject of the clinique, and of these lithotrity had proved beneficial to six.

A Learned Company, Limited.

A PROJECT is on foot for the erection of a good building for the use of the learned societies. The want of accommodation for Science is notorious, and as the State is not likely to help we welcome a limited company.

Case of Laryngeal Stenosis Cured per Vias Naturales.

THE *Gazz. Med. Ital. Provin. Ven.* records a case of which the following is the substance. Dr. Massei had under his care a person, æt. 40, in January, 1872. The patient had contracted syphilis in his youth, and had had manifestations of it at various times and in divers places, the throat suffering among others. He had undergone the mercurial treatment, and subsequently had taken iodide of potassium. Dyspnœa afterwards slowly became developed, for the cure of which intra-laryngeal application of sol. arg. nitr., and of electricity were employed with benefit to the difficulty of speaking, but not of the dyspnœa. Laryngoscopic examination showed neoplastic bands stretching from the false to the true chord. vocal., with detritus of mucus, &c., between. The treatment was begun by incising the bands with Mandi's scarificator. The respiration was markedly improved. Electricity was then employed by means of Mackenzie's electrode, daily for one month, every second day for another month, and twice weekly for a third. The case improved in every way under this treatment, the rima glottidis assuming almost its normal size.

DR. LLOYD ROBERTS, Physician to St. Mary's Hospital, Manchester, has been elected a corresponding member of the Obstetrical Society of Berlin.

DR. RADCLIFFE will lecture at the Royal College of Physicians of London on Wednesday next at 5 o'clock "On Mind, Brain, and Spinal Cord in certain Morbid Conditions."

THE Medical Society of the College of Physicians of Ireland will meet this evening. The following communications will be made to the society:—1. Dr. McClintock "On the Semeiology of Intemperance;" 2. Dr. Eames "On a Case of Combined Spasm and Anæsthesia."

IT has been proved by M. Pouchet, experimenting on fish, that their colouration is in great part due to the action of light transmitted by the eye to the nervous system, and so to the colour cells of the skin; by section of certain cutaneous nerves M. Pouchet was enabled to interrupt the nervous vibrations and render the parts answerable to the stimulus of the surrounding medium, and by this means produce zebra-coloured fish.

THE annual meeting of the Royal Medico-Chirurgical Society of London has gone off with its usual *éclat*, and Mr. Curling, F.R.S., took his leave of the Presidency in an address which gave satisfaction to all. He naturally spoke among other things of the two great topics that had signalised his year of office, vaccino-syphilis and arterio-capillary fibrosis. Of both of these debates we have given such full accounts that it is unnecessary to allude to them further.

The death-roll of the year always claims a place on these occasions, and Mr. Curling had to notice the decease of the following Fellows of the Society who have died during his presidency:—

Dr. James Alex. Gordon, Dr. C. J. B. Aldis, Mr. F. C. Skey, Mr. Alfred Poland, Mr. Thomas Hewlett (of Harrow), Mr. Martin Ware, Mr. James Startin, Mr. Holmes Coote, Mr. Caleb Burrell Rose (of Yarmouth), Dr. Alex. Browne (of Kirkcudbright), Mr. James Spark, Mr. William E. Masfen (of Stafford), Mr. Weedon Cooke, Mr. Bowyer Vaux (elected in 1806, and the Senior Fellow of the Society), Dr. T. T. Roscow (of Brussels), Dr. John Davies (of Hertford), Dr. Benjamin Godfrey (of Enfield), Mr. W. R. Cooke (of Slough), and Dr. James Walsh (of Limerick).

After the address the formal business of the Society was got through, and the following officers and Council were declared to be elected for the ensuing year:—President: Dr. C. J. B. Williams, F.R.S. Vice-Presidents: Dr. A. W. Barclay, Dr. Sieveking, Mr. White Cooper, Mr. J. A. Kingdon. Treasurers: Dr. Wegg, Mr. John Birkett. Secretaries: Dr. Symes Thompson, Mr. Cooper Forster. Librarians: Dr. Sibson, Mr. Timothy Holmes. Other Members of the Council: Drs. Frederick Davies, H. J. Sanderson, C. J. Hare, J. W. Ogle, Owen Rees; Messrs. William Adams, Thomas Bryant, W. O. Chalk, J. T. Clover, and Edwin Saunders.

Literature.

POSOLOGICAL TABLES (a).

THE intention of Dr. Griffiths in issuing these tables would appear to be to supply the Profession, especially dispensers and Poor-law Medical officers, with a convenient and ready means of information as to doses when they are in the act of prescribing or compounding, and where access to the Pharmacopœia or to Macnamara's Medicines would be troublesome and tedious.

Having this object in view, Dr. Griffiths has issued his tables in the form of a wall chart, and has grouped the agents and pharmacopœial preparations according to their medicinal form, and not by their chemical or therapeutic relationship. By this means Dr. Griffiths has been able to condense the information and make it more immediately comprehensible, and, by the addition of Gaubin's and Young's calculations of the comparative doses for children, has perfected the chart. Dr. Griffith's tables should be especially useful to practitioners, who are obliged to prescribe and dispense at the same moment, and, it strikes us, would be of great convenience to the dispensary physicians of Ireland, and a valuable safeguard against mistakes which might occur in the hurry of daily work. The Local Government Board might advantageously consider the propriety of supplying each dispensary and workhouse in Ireland with a copy, the cost of which would weigh little against the benefit which such ready information would be to the service. The chart is carefully compiled and creditably turned out, and is a desirable addition to the prescriber's *armamentum*.

(a) "Posological Tables": being a Classification of the doses of all officinal substances for the use of students and practitioners. By W. Handsell Griffiths, Ph.D., L.R.C.P., Assistant Librarian to the Royal College of Surgeons in Ireland.

CLINICAL LECTURES ON DISEASES PECULIAR TO WOMEN (a).

THIS re-issue of Dr. Atthill's sterling little book, the notice of which in our columns has been unavoidably delayed, follows quickly on the heels of his first edition, and within little more than a year from the publication of the lectures in the MEDICAL PRESS AND CIRCULAR, the revised edition is in our hands. A quick sale, such as Dr. Atthill's book has met with, is seldom the lot of Medical works, and is an assurance that the author has been happy enough to provide the Profession with literary food, suited to its digestion and its taste. Dr. Atthill's lectures are apparently written to be read and not to astonish the reader with a display of erudition—an object which is the *raison d'être* of many books. He gives as plainly, concisely, and exhaustively as possible the results of his reading and practice, without thinking it necessary to interlard a German professor, or a reference to some unheard-of authority into every third line, and his book is accordingly relished by plain people and busy practitioners. The author has added an important chapter on enlargements of the uterus, and has otherwise rectified sundry omissions in his first issue, and has produced a little book which does him credit, and which bids fair to be a standard manual of the diseases on which he writes. Dr. Atthill's first effort at book publication has advanced him to the foremost rank of obstetric writers, and leads us to hope for many valuable additions from his pen to the literature of gynæcology.

◆

Correspondence.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your impression of the 26th of February last, I observed that the Council of the College intend to make progress regarding "the members left out in the cold." I think an act on the part of the Council, which I beg to suggest, may be satisfactory to members elected *without examination many years* ago, is that the Council offer to all members elected as stated, the Fellowship of the College, if they accepted it.

Yours truly,

M.R.C.P.

London, March 6th, 1873.

THE COPYIST AND ORIGINAL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I beg to hand you a statement for kind insertion in your columns, as a record of advance in microscopical science. In support of my statements therein, I am ready to deliver a lecture on the "History, Progress, Present State of the Science, and proposed future study of the subject," with discussion afterwards, before any class of persons, if sufficient interest therein can be collected within four walls.

I am, Sir, obediently yours,

WILLIAM PARKER, M.R.C.S.

11 Southcot Place, Bath, 17th Feb., 1873.

"Sir Christopher Wren and Dr. Anthony de Leeuwenhoek, F.R.S., were born in 1632, and died in 1723, aged 91 years. A brief account of each may not be amiss in these days of professed scientific enterprise and research amidst acknowledged defects in art and design, by Mr. Forster, in *Fraser's Magazine*, December, 1872, and Sir Arthur Helps at Portsmouth, in these words, "Let us get rid of inaccuracy, &c.," on the occasion of his distributing prizes in a school of art.

"We will begin with our own countryman, the first esteemed architect by the public, and conclude with the Dutch naturalist, the little, or not esteemed by scientific men, especially by the microscopists of the day. The 'London Encyclopædia' supplies us with the following:—"Sir C. Wren was the son of Christopher Wren, Dean of Windsor, and was born in 1632. He studied at Wadham College, in Oxford, where he took the degree of A.M., in 1663, and was chosen Fellow of All Saints' College. In 1657 he was made Professor of Astronomy at Gresham College, London, which he resigned in 1660, on his being chosen to the Savilian Professorship of Astronomy in Oxford. He was in 1658 created LL.D., and in 1662 was elected F.R.S. He was one of the commissioners for the reparation of St. Paul's, and in 1665 travelled into France (and Italy) 'to examine the most beautiful edifices there, when he made many curious observations.'' We here see a good beginning of the great man from his birth onwards, and the world has largely esteemed his fame as an architect of public buildings in London. The whole, or his chief works, are the resulting of copying from others, or result of natural talent, from which no detraction can be offered. Dr. Anthony de Leeuwenhoek was a celebrated Dutch physician and naturalist, born in Delft, 1632. He was of an ancient family, and acquired great reputation throughout all Europe by his experiments and discoveries. He particularly excelled in making glasses for the microscope and spectacles. He died in 1723. His letters to the Royal Society of London were printed at Leyden, in 1722, in 4to.' This brief account of the foreigner is no very great amount of praise or inducement for men of the 19th century to look further into his merits, as we shall show by microscopists of the day, entirely ignoring his beautiful objects of illustrations, in proof of this statement. The late Mr. Thos. Joseph Pettigrew, F.L.S., sold Leeuwenhoek's work by Samuel Hoole, in 1800 (in my possession), some years before he died, in 1865, and Dr. Carpenter has excluded Leeuwenhoek's illustrations in his three editions of microscopical display; Dr. Lionel Beale, Mr. Erasmus Wilson, and others of equal public notice also exclude Leeuwenhoek's illustrations of nature, which is the same now as 200 years ago; furthermore, the Quekett, Bristol and Bath Microscopical Societies are frequently at a loss for interest in the science because they ignore Leeuwenhoek. With these considerations of exclusion what degree of merit can there be given to outsiders, viz., literary men unconnected with microscopical science? none whatever. Thus we have a 'cold blanket' cast on the greatest naturalist and microscopist on the animal, mineral, and vegetable kingdoms, up to his death, that ever lived in any country, so far as his history and works show us.

"*Fraser's Magazine* contains an article 'On the True School for Architects,' by Forster. Quoting the following:—"'There is one school,' cried Hogarth, 'and that is kept by Nature.'" The subsequent remarks of the author tell us of '*a solution of all our difficulties*,' without his giving a single solution, besides in building palaces and chateaux, which may have been copied from Galen about A.D. 131. Thus, the literary man is nowhere in the science of Nature—Physiology, having supplied the Right Honourable W. E. Forster, M.P., with ten specimens of microscopical drawings from Nature by Leeuwenhoek for the purpose of superseding present plans of patterns of nothing, as adopted in schools of art, and receiving a brief acknowledgment only. It now remains to be seen whether any alteration in our schools will take place. The contrast between Sir C. Wren and Dr. Leeuwenhoek will be more clearly seen by asking which man should have the greater merit—the one who is a copyist, or the one who is an original?"

ECONOMY IN COALS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—You are perfectly right in your remark on your correspondent's suggestion for the more economical use of coals by the *solid iron-plate* bottom stove. The suggestion is by no means new, as I am, however, perfectly convinced of its value, you will perhaps permit me to say that I got Messrs. Adams and Son, of the Haymarket, to make a stove for me on this plan for the wards of the Charing Cross Hospital some three or four years ago. This stove has in every way answered my expectations in economising fuel, and as a means of enabling us to maintain better ventilation in the wards. My experience of the solid iron bottom stove in my own house also enables me fully to corroborate your view, that "it should be more widely known and adopted."

(a) "Clinical Lecture on Diseases Peculiar to Women." By Lombe Atthill, M.D., Univ. Dub., Obstetric Physician to the Adelaide Hospital, Examiner in Midwifery in the King's and Queen's College of Physicians in Ireland. Second Edition, revised and enlarged. Dublin: Fannin. Crown 8vo, pp. 241.

I enclose you a drawing of the stove, and which can be seen in use at the hospital. The grate consists of an open fire, with a *solid iron bottom plate*, sides lined with fire-brick, or Stourbridge-lumps, at the back, and immediately over the fire, is a small aperture communicating with the flue, which forms the only exit for the products of combustion. The fire is fed with coal or coke (any kind of combustible rubbish will burn in these stoves), placed as near the front bars as possible, the smoke from which, passing over the clear fire behind, is immediately converted into a flame. If this plan of feeding is observed the stove is practically converted into a smokeless grate. The upper part of the stove, as seen in the drawing, is especially adapted for hospital use. It is a hot closet, deep enough to take a dinner plate, and has been found very useful for keeping a patient's meal hot for a long time without deterioration, should he or she be unable to take it when it is sent up to the ward. On each side of the hot closet is a ventilating grating, by means of which a current of fresh air is admitted into the ward, having first been thoroughly warmed in its passage from the external part of the building by passing up the back and sides of the grate. The *hob* is retained for the convenience of convalescent patients and nurses, who prefer making their own tea; kettles or saucepans of hot water are thus always kept ready for use. The coals being almost entirely consumed, a small ash-pan receives the white ash which falls, and keeps the fireplace always clean and tidy. The stove, I am convinced, generates four times the amount of heat of those formerly in use in the wards; it ensures an equal circulation of pure air, with perfect freedom from dust and smoke; a great saving of fuel is the result, the fire requiring less feeding, and every particle is completely consumed. In a private house, the stove should be *set well out in the room*, the draught obtained by the narrow aperture communicating it with the chimney removes all danger of smoke rushing back into the room, let the wind be ever so gusty. In this way, too, the heat generated is equally distributed and retained in the room—not lost and driven up the chimney as in the old-fashioned grate.

I remain, yours most obediently,

Bedford Square, Feb. 15, 1873. JABEZ HOGG.

SECRET POISONING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Upwards of twelve months since, my attention having been directed to this subject, an article from my pen was published in your valuable journal on the 1st of January, under the title of "The Arts of Secret Poisoning," practised by the Thugges of India, whose use of *Aqua Tofana* was alluded to, as also an extract then given from *Parson's*, the Jesuit's, *Leicester's Commonwealth;* cited from Sir Walter Scott's "Kenilworth," under letter G in the appender title Dr. Julio, in reference to which contribution you were pleased to remark that the paragraph under this head was "inserted in deference to the very distinguished position of your correspondent, but that you were of opinion that we are not in such danger as supposed from these practises."

Subsequently, another article appeared in your journal on the ensuing 6th of March, under the heading of "Secret Poisons," referring to Oliver Goldsmith's letter, No. 106, in the *Citizen of the World*, and also to an article in the *Saturday Review*, upon the same subject, followed by an extract from the *Daily Telegraph* of the 28th of the previous month, detailing the very sudden death of General Cugia, from the effects of poison, supposed to have been administered in a nosegay, intended for the Prince Umbert, "and to the expressed opinion of an English resident" *that such things were not uncommon in Rome*, and also alluding to the averment of a Monsignore "that there would be more of such attacks," which the clerical papers of Rome designated "*as the finger of God*," and which circumstances now lead me to revert to these reminiscences of last year's events.

It is not a little singular, that the Archbishop of Canterbury in his subsequent sermon at St. Paul's, on the Public Thanksgiving Day, for the recovery of H.R.H. the Prince of Wales, made use of the same stereotyped expression "*the finger of God;*" and, if I remember rightly, at a funeral sermon preached at Reading on the occasion of the death of the late Prince Consort, the Prelate of Winton made use of a similar expression, in rather stronger language, namely, *the judgment of God*. As the Imperial Princes of Russia and Prussia, have each, since the recovery of H.R.H. the Prince of Wales, equally suffered from the same inscrutable but not altogether unexpected malady, it may not be considered amiss to give an extract from Sir Walter Scott's "History of Scotland," of an incident (which most probably led to his having introduced the character of the clandestine poisoner in his romance of "Kenilworth"), and which is cited from "The Secret Correspondence of Sir Robert Cecil with James VI., King of Scotland, page 190."

The circumstance that Sir Robert Cecil carried on this correspondence is stated by Sir Walter to have been a "secret that was, however, carefully kept, although at one moment upon the verge of transpiring," under the following circumstances:—"Queen Elizabeth was taking the air in a carriage where Cecil occupied a seat, when one of the Royal posts passed them." "From whence?" the Queen demanded; and the answer was, "From Scotland." "Give me your packet," said the Queen. It was delivered accordingly. "Open it," said she to Cecil, "and show me the contents," As the packet contained some part of Cecil's correspondence with the King of Scots, this command placed the crafty statesman within view of ruin and the scaffold. To have attempted to suppress or substract any of the papers which the packet contained, would have been a hazardous experiment, in the presence of the most sharp-sighted and jealous of sovereigns. Cecil's presence of mind found an expedient. "This packet," said he, as he pulled his knife out to cut the strings with which it was secured, "*has an uncommon odour, and must have been in some filthy budgets.*" The Queen was alarmed; she had been all her life delicate in the sense of smelling, and was apprehensive of *poison which she believed could be communicated by that organ.* "Take it," said she to Cecil, "and let it be aired before the contents are presented to us." The wily secretary obeyed her commands, and obtained the desired opportunity to withdraw such papers as he deemed it important to conceal.—*Lardner's Cyclopædia, edition* 1857. *Vol.* 2., *pp.* 421-3.

It may be allowed to be remarked that history repeats itself, and having since seen two English friends who have both had considerable experience in Italian life, and were resident in Rome at the time of the death of General Cugia, they were each strongly of opinion that "*the finger of God*," was a metaphorical expression intended to convey an opinion that a death had occurred; but not quite according to the ordinary laws of nature—in the just defence of Sir Walter Scott's views on this subject.

I am, yours, &c.,

VINDEX.

NITROUS OXIDE DEATHS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I now enclose the three letters of Dr. Chas. Kidd to which I referred in my last communication, and I trust that in justice to him and to me you will print them, in order that your readers may judge whether I have in any way misrepresented him. It will be remembered that my charge against him was that he had put forth in one letter emphatic statements with regard to the comparative safety of various anæsthetics, and had contradicted these statements in the next, and that he had employed expressions calculated to cause unnecessary alarm in the mind of the public, and so to restrict unduly the use of nitrous oxide—an agent which thus far has proved of incalculable service in mitigating suffering and in curing disease. Dr. Kidd does not now deny that his "impressions" did suddenly vary, but he says that his opinions are not worthless because he has changed them; and he implies that I think that the judgment of men who conscientiously change their opinions is valueless. I respect conscientious opinions based upon reason however often they may have been changed, but I object to the reckless publication in the daily newspapers of vague assertions on matters of Medical science unsupported by facts or by argument and totally opposed to the deliberate opinions of eminent men—opinions arrived at after profound research and exhaustive discussion.

Dr. Kidd reiterates the statement that there have been four deaths from nitrous oxide. In answer to this, reference may be made to the second report of the Committee read at the November meeting of the Odontological Society. At page 31 of that report the Committee say that "out of the thousands of cases of its administration of which they have records, and the thousands of unrecorded cases both in *this and other countries*, not a single death referable to this gas has occurred." It is true that at the December meeting of the Society Dr. Kidd remarked that one death had taken place; but when challenged to authenticate it he could only reply that it happened in America. If Dr. Kidd wishes us to believe in these deaths he must give the dates and the names of the administrators, together with an account of the legal inquiry which in America as in England would be certainly held.

If Dr. Kidd in his *Daily News'* letter meant after all that the gas was "safer in proper hands than any other anæsthetic," and that it was "only in hands of the average dentist's assistant" that it was more deadly than chloroform, he certainly did not say so—as may be seen by reference to the correspondence. This statement, as well as another in Dr. Kidd's letter in your last, "that in chloroform accidents, the scientific mode of arresting danger seldom or never fails in saving the patient," is, however, altogether wrong. The gas has been used to an enormous extent by unqualified practitioners, many of whom are barely acquainted with the physical signs of anæsthesia, and who could not distinguish between syncope, apoplexy, and mechanical asphyxia. Yet the Exeter fatality is the only one directly or indirectly due to the gas which has occurred in qualified or unqualified hands. Chloroform, on the other hand, causes frequent deaths although never given except by Medical men. Moreover, it is admitted by the best writers—including Dr. B. W. Richardson, the highest living authority—that the mortality from chloroform appears to be a necessary mortality, just as there is a mortality from accidents and acute diseases; that it is impossible to predict the result of any case in which the agent is used; and that patients die under it who are entirely free from organic disease, whilst others of extremely feeble constition inhale it repeatedly with safety. These writers also unanimously agree that when a fatal issue is impending from chloroform we are frequently powerless to avert it. The last death from anæsthetics in London furnishes an instance in point. The admistrator was a surgeon of the highest qualifications and of great experience, and there were present three or four first-rate surgeons. Before the patient had lost consciousness, suddenly the pulse became irregular, then stopped. Proper means were instantly adopted and were persevered in without result—the patient was dead. No warning sign existed before the administration, and no organic disease sufficient to account for death was discoverable at the *post-mortem* examination. If Dr. Kidd knows of any "scientific method" of preventing accidents of this kind, of which at least one has occurred in the experience of most chloroformists, it is to be regretted that he has not yet published it for the benefit of suffering humanity.

Your obedient servant,
HENRY SEWILL, M.R.C.S., &c.
6 Wimpole Street, W., March 7th.

[Pressure upon our space precludes the insertion of the letters from the *Journal of Dental Science* and the *Daily News* referred to by our correspondent, but we may remark that the statements in Mr. Sewill's letter are fully borne out. The fact that this one death, out of perhaps a million cases, has created such an unusual amount of interest and controversy, proves to demonstration the value of the anæsthetic attacked; and here the correspondence must close in our columns. Having on several occasions protested against the proclivities which certain members of the Profession display for rushing into the daily press upon matters which should only be discussed in Medical journals, we would instance this as a case in point, and express a hope that those whom "the cap fits" will for the future refrain from such unprofessional practices.—Ed.]

"ECONOMY OF COAL."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In "Notices to Correspondents" in your issue of the 12th inst. (which I have only now seen), there is a paragraph under the above heading which, as it embodies a very prevalent delusion, I do not think ought to be allowed to pass unchallenged in a scientific journal.

All such expedients as "metal plates at the bottom of the grate" and those so-called "fire-balls" made of vitrified earthenware, are mere shams. The first can only act by exclusion of the air, an essential element of combustion, and simply prevent that process going on actively, and *pro tanto*, diminish the evolution of heat while augmenting the smoke, which means waste of that very dear commodity coal.

The "fire-balls" are simply "a mockery and delusion" only suitable for genteel people who like the appearance of a large fire in their sitting-rooms, while in reality it is a very small one, and the room a very cold one. Being non-combustible they cannot evolve heat, and the common fire-clay backs to modern grates serve the purpose of retaining heat much better.

It would be very obvious to any one familiar with chemical laws that merely withholding one of the elements of combustion cannot be economy except in so far as it is an economy of heat, or absence of it rather. If people must have a fire let them get a grate judiciously constructed, proportioned to the size of the room, and then, by a little care, keep the coals burning with as little smoke as possible, or if they still will believe in "metal plates" and "fire-balls," let these expedients be tried by their cooks. I venture to say these sapient and cozy individuals will soon give their mistresses "a bit of their minds" when accounting for raw meats.

I mention the subject because I heard it all discussed in a railway carriage some time ago by two intelligent gentlemen; both seemed gratified by the interchange of economical nostrums. I professed to listen, but have since speculated on the possibility of their trying both expedients at the same time diminishing the coals to a minimum and the oxygen ditto —a comfortable look out of a cold day.

Your obedient servant,
Dublin, Feb. 19, 1873. L. D.

[Our Correspondent is quite right in theory, but suppose "genteel" people want to have a cheerful fire at a low price and are content with a moderate temperature, the "economical nostrums" may be a better alternative than a miserable little grate with capacity for a handful of coals which fly up the chimney in a minute or two and leave desolation and shivering behind.—ED. M. P. & C.]

◆

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Would you kindly inform me if there is any work which treats at some length on the different departments of our Medical Profession. I have made repeated enquiries concerning such a publication, but always with the same unsuccessful result, so I now consult you, hoping that you will be able to lend me your valuable assistance. If such a work be not published, is certainly shows a great blank in our literature, as in my humble opinion there is no book whieh would be so valuable to a young doctor about [illegible] the world.

I am, Sir,
yours faithfully,
A YOUNG SURGEON.

[There is no such work as our correspondent indicates, although its utility would be undoubted. Mr. Baxter Langley's "Via Medica," is a complete treatise on one part of the subject, the relation of Medical assistants in England to Medical Practitioners. A small book published by Edmonston and Douglas, of Edinburgh, under the title of "Everything about them," gave a very succinct and intelligible account of the Naval Medical Service as it then existed. The Student's number of the MEDICAL PRESS AND CIRCULAR, is the only publication which contains any practical epitome of the whole subject.—ED. MED. PRESS.]

HOSPITAL GANGRENE (*a*).

By Mr. Arthur E. Barker.

Mr. President and Gentlemen,—In the few notes which I have the honour to bring before the society this evening there can be but little which might be called entirely new; and yet let me hope that the description of the nature and treatment of a disease formerly better known owing to its frequency, and now but rarely met with, thanks to the advance of Medical science—let me hope, I say, that a short description of this affection, as observed by myself, a young member of the Profession, may not be without a purpose, as showing that we are not yet rid of a scourge dreaded so much by surgeons of an earlier time, and which we had begun to imagine we might never again be called on to deal with, owing to our improved sanitary arrangements.

These few remarks may be of interest in another way; they may serve to remind us of the vast importance of the most rigorous attention to hygienic measures wherever many human beings suffering from wounds, whether surgical or otherwise, are brought together—a fact which cannot be dwelt on too often. They may serve to cheer us also with the contemplation of the advances made by modern Medical science towards the extermination almost, of certain diseases in these countries, formerly of frequent occurrence, and stimulate us further to fresh endeavours to bring our sanitary arrangements to a higher state of perfection.

I do not deem, then, any further apology necessary for presenting this society with a short sketch, however humbly and imperfectly executed, of that terrible disease, Hospital Gangrene, as it came under my own notice.

Gentlemen, it may be advisable, before giving you the substance of the notes taken at the time, to devote a very few words to the circumstances under which this affection made its appearance.

During the late war between France and Germany the fearful numbers of wounded to be attended to, necessitated their being massed more or less at those points where Medical and other aid could be most easily procured, and thus most towns came in for a large share of them. In that small town in which my lot was cast, whose population amounted to 22,000, we had treated, a few months after I had been there, over 4,000 severely wounded. Among these the mortality had been smaller than in most other towns, although all the most terrible injuries which can accompany war had passed under treatment. This, I have no doubt, was partly owing to the general healthiness of the locality and partly to the fact that the liberality of the richer classes, who are largely represented in that neighbourhood, supplied not only necessaries but comforts to the victims of the war, not so easily procurable in other parts of the country.

Otherwise, things were pretty much as elsewhere, that is to say, the Medical assistance must have been supplied from the same class as at other places, and the shelter of various kinds hurriedly provided for the reception of the wounded was as multifarious in its nature as could well be conceived. Thus we had empty private houses turned into Lazarets, public houses, saw-mills, a brick-mill, a riding-school, and wooden huts. These were fitted up, as well as possible in such haste and excitement as then prevailed, with stoves and beds obtained, for the greater part, from the barracks left unoccupied by the departure of the hussar regiment always quartered there. At first, of course, the men had to be put up on straw laid on the ground.

In the remarks which are about to follow, reference will be particularly made to two Lazarets in which I was myself active, and in which alone the hospital gangrene made its appearance. In one of these, an old tumbled-down public-house, built of wood, there were between forty and fifty men suffering from the usual wounds inflicted by the weapons of the present day. Here might be seen bullet wounds in all parts of the body, others produced by shells, &c.; fractures, simple, compound, compound comminuted, and so on. In the other Lazaret, metamorphosed between morning and night from a riding-school, with its racks round about and straw on the ground, into a large sick

---

(*a*) Read before the Surgical Society of Ireland.

room, with one hundred and twenty severely wounded, there were as I joined between ninety and one hundred suffering from all kinds of mutilation.

Of these men the greater part may be said to have been progressing favourably at the time at which the gangrene made its appearance. Some had been struck in the first engagements, and were already walking about; others were sitting up and able to read; while the lighter wounded were many of them able to take part, to a certain extent, in the easier offices of attendance on their maimed comrades.

Things were in this state as we heard of the approach of a hospital transport train coming from the north of France, from which we were to receive about forty or fifty men, who had, for the greater part, been wounded in those fierce fights about Amiens, St. Quentin, and Bapaume.

Being near the railway-station at the moment of arrival of this train I went with the first of those who were being lifted out and carried on stretchers to the nearest of the Lazareths mentioned, which was about sixty yards from the station. Here we were engaged from about three o'clock in the afternoon until nine o'clock in the evening in getting the men arranged in beds and taking off their bandages, some of which had been left on three days without change. Almost the whole lower extremity of one unfortunate was found like a vast boggy slough, within an enormous plaster-of-Paris bandage, in which it had been encased tightly for several days with but little attention. In consequence of this it had to be removed on the second day following by the circular operation at about the junction of the middle and lower thirds of the thigh. The patient died, however, on the next day, apparently of septicæmia. No trace of reparative action could be seen in the dirty-looking flap. This death was followed a few days after by another, caused apparently by the same disease, in a man wounded in the hand.

I mention these few points merely to show the state in which we received the men. They were most of them much depressed and weak, and had been for some time but very insufficiently dressed and otherwise attended to while at Amiens, owing to the numbers to be looked after. At this town the gangrene had already broken out.

The second Lazaret referred to, which I visited in the morning, had also received several of the same set of men, who, though as weak and broken, could hardly on the whole be said to be in so dangerous a state as those first mentioned. These patients were distributed through the ninety men already in the riding-school.

Neither in the large building just alluded to nor in the other near the station had the hospital gangrene made its appearance at this time; but a few days after, some of the wounds presented appearances unfamiliar to the doctor whom I was assisting, but which were sufficiently extraordinary to cause him grave apprehensions. He had never seen hospital gangrene before, and did not recognise the affection as such. The timely arrival of the surgeon-general a day or so afterwards, however, settled the question beyond doubt, as he had dealt with the matter at its source in France. By his directions, the first man attacked was isolated completely from the others, and put by himself in one of the fifty huts just completed on the adjacent parade-ground for the reception of French prisoners.

This, however, did not prevent the spread of the disease, for within a short space of time three or four men were one after another infected, among whom was one who had been wounded in the arm at the commencement of the war, and who was almost quite recovered; the fracture of the humerus being united by a large mass of callus.

All this being quickly remarked, and also that only those patients were attacked by the malady who were under the care of one particular Medical man and his assistants, more perfect and effectual isolation was resolved on. I was considering the advisability of offering myself to take charge of these men in the huts, giving up my evening visits to the Lazaret at the other side of the town, and avoiding all communication with the main building or any of its staff, when I was asked by the surgeon-general and the Medical man, Dr. Alfter, whom I was assisting, to do this very thing.

Two assistants were then told off to aid me, with orders not to enter the riding-school or any of the other Lazarets, and not to employ any basins, buckets, or other utensils but those given out specially for their huts.

There were now seven men in the first hut severely affected, and the disease seemed to spread no farther in the main building, if we except several other cases which about the same time were removed to a neighbouring shed on account of their wounds looking very suspicious. In these, however, if the process had been set up, it ran but a short course, and soon disappeared.

The disease now made its appearance in the Lazaret first referred to as situated near the railway-station; but its dangerous nature being at once recognised by Geheim Busche, the surgeon-general, the single case was promptly carried over to the hut in which the other seven men had been placed. The man affected had also been wounded at St. Quentin, and had arrived from Amiens by a transport train with some of the others. His large wound, caused by amputation high up in the thigh, appeared, however, at the time of arrival perfectly healthy. This renders the fact of his being subsequently attacked by the gangrene of some interest, as there was no communication between the two Lazarets, except Dr. Busche's visit, which, as he said himself, he never made on the same morning on which he had been to see our patients at the riding school.

The isolation may now be said to have been complete; the many Medical men engaged were on their guard, and the gangrene spread no farther.

Turning now to the consideration of the disease itself, I shall endeavour to sketch briefly the outlines of its mode of commencement, its course, and the treatment adopted; taking the notes of four or five of the severest cases to illustrate what was observed.

The following short description of the manner in which the process commenced in wounds is the substance of an imperfect sketch made at the time:—

In those cases in which large wounds already found were attacked by the disease, the granulating surfaces may have been looking very healthy until then, and covered by laudable pus. The commencement of the gangrenous affection was then indicated by the granulations assuming at certain points a peculiar "lardy" appearance, like the fat of raw bacon, as the word "speckig," made use of among Medical men there, signifies. At these portions an exudation somewhat similar to that of croup was thrown out, and adhered to the subjacent granulations with great tenacity. This thin elastic coating could be peeled off with some difficulty, but its removal gave rise to considerable oozing of blood from the raw surface underneath. The edges of the wound then became of a dusky tint, and at first slightly elevated. Then the connective tissue between the skin and muscles began to break down, with the formation of a thick curdy pus, which required to be squeezed out from under the skin. The latter now appeared folded in round the edge, being completely undermined; then holes were formed in it and enlarged until the whole edge broke away. In some cases the skin so undermined became again adherent to the surface underneath, remaining so for a shorter or longer space of time, perhaps days, sometimes, however, loosening almost immediately again.

In most instances the muscles manifested considerable capability of withstanding the corroding influence of the morbid action, more even than the other tissues, as, for instance, the aponeurotic structures. They could be seen lying in the wounds completely denuded of areolar tissue, and covered with heavy florid granulations. In the case of Ludwick Rodeck, to be referred to presently, the large muscles of the calf were regularly dissected out, while between them and back behind the tibia, which was laid perfectly bare for about three inches, large slits were formed where the areolar tissue and other inter-muscular structures had suffered; the latter could be drawn out with a forceps in long shreds.

The bones, which were laid bare in several instances, presented nothing peculiar in appearance, except, perhaps, that while the destructive process was going on at the edges of the wounds, they threw out granulations from their surfaces, pointing to the fact of the existence of an effort at reparative action at one spot of the wound, while fearful ravaging of the tissues was going on at other parts of the same. The re-adhesion of undermined skin indicated something similar.

The different forms into which this affection has been divided could well be seen here; they seemed, however, to depend more upon the position of the wounds than on any difference in the nature of the morbid action. Thus, the creeping or spreading form was observed at those points where much areolar tissue was interposed between the skin and subjacent structures; while the burrowing or penetrating action was remarked where much fatty or cellular tissue passed into the substance of the limb, as in the case of Jacob Kralzak, who had a large cavity in the neighbourhood of the ante-cubital fossa, while the extensive wound on the outer and back portion of the elbow-joint spread rapidly without growing much deeper.

On the whole there was not apparently much suppuration, and the pus seemed to adhere at many points to the surface of the wound. At other portions, the latter presented a peculiar appearance; islands of raw surface were to be seen in the midst of the granulations; these did not present the ordinary characters of granulating surfaces, but were simply red vascular patches, perfectly clean, having more the appearance observed in deep abrasions of the skin.

While rapid destruction of parts was going on but little pain was complained of, but on the process becoming checked in any way, the suffering seemed fearful, if one is to judge by the incessant shrieking which accompanied the most careful dressing. This I shall never forget. Notwithstanding the gentlest manipulation of the two assistants and myself, the men generally shrieked up in our faces from the moment the limb was lifted until the dressing was finished, and so loud as to earn for the hut in which those bad cases were placed the title of "the chamber of misery" from those outside.

The pulse, during the increase of the disease, was high, ranging from 120 to 145. One point which I find dwelt on briefly in those jottings made at the time may be mentioned here, namely, the remarkable fall in the pulse, lasting for some time after the severe cauterisations to which many of the cases had to be subjected. I find the [illegible] note in my book made on the evening of the last [illegible] which case No. 2 had been cauterised. About [illegible] irons at a white heat and varying in size had been [illegible] very severely to the wounds. The pulse for several days previously had ranged from 115 to 120 :—Evening.—Pulse 90. Complains of no pain. It is remarkable that the pulse has become slower in each case [illegible] application of the actual cautery; the same was observed to take place with the other men who were [illegible]. On the evening of the day following the pulse [illegible] again risen to 112."

As regards the rapidity with which the tissues were destroyed, I find the following brief note among my papers :—

"Nothing analogous would give an idea of the rapidity with which the disease can spread at times, even after having remained stationary for a considerable period. Of this we have an example to-day in the case of Heinrich [illegible]kohl, whose two wounds, situated one upon the back of the upper arm, and the other on the posterior and external surface of the forearm, seemed the day before yesterday to be stationary. Chloride of zinc had been applied [illegible] the day previous, and the wounds for the following days were dressed with wet charpie alone. [illegible] the edges were further undermined, but to-day the two wounds, formerly separated from one another by [illegible] skin about three inches broad, had almost become [illegible] ulcer. The edges, for more than an inch in [illegible], were quite undermined, falling in all round, [illegible] requiring to be pulled or cut away before applying the actual cautery, which was energetically used under chloroform."

The usual appearance presented by the pus in those parts yielding rapidly to the process of corrosion was that of curdy whey. It was not, however, poured out in any large quantity as a rule, but could be squeezed out from under the edges in the form of thick whitish clots, mixed with an ichorous fluid.

The duration of the destructive morbid action, judging from a comparison of the cases in my note-book, appears to have been from four to six weeks. This is reckoned from about the time at which it became apparent that a gangrenous process had commenced in the wounds, until that period at which the same seemed to progress no farther, or to be extinct.

Before referring more particularly to the treatment employed in the various instances, I shall, with your permission, devote a few moments to the briefest possible digest of four or five cases taken from my note-book, commencing with that of the man in whom the disease first manifested itself.

(To be continued.)

LICHENOID ECZEMA OF THE FACE CONNECTED WITH THE ATHRITIC DIATHESIS, PROBABLY DUE TO LACK OF INNERVATION OF THE FIFTH PAIR OF NERVES.

By F. M. Luther, M.D., Cappoquin, co. Waterford.

I have arrived at the conclusion that defective innervation of the fifth pair of nerves, caused by cerebral congestion, is a chief cause of lichenoid eczema of the face, which cerebral congestion again is due to the action of the rheumatic or gouty diathesis, latent or suppressed. The poison, instead of locating itself in the joints, floats about in the system, and is in some cases arrested in the brain, causing, with other disagreeable symptoms, want of sleep, and following on this, with so much regularity, as to look like cause and effect, a lichenoid eczematous eruption most noticeable at the termination of the lashes of the fifth pair of nerves, and which is more amenable to treatment by cholagogue or alöetic purgatives, followed or alternated by chloral draughts, so as to ensure sleep, and abate the cerebral congestion, than to any other method of treatment. As acidity impedes the hypnotic action of chloral, I usually direct a glass of fluid magnesia to be taken half an hour before it. Probably, in the case indicated above, alkaline bitters, potash, or soda and gentian, taken thrice daily, would contribute to hasten the cure, by relieving in some measure the dyspepsia which, if not the "fons et origo malis," at all events reacts upon the brain; but, in those conditions of depressed cerebral power, the patient is too apathetic to take any remedy three or four times a day. Purgatives alternated with chloral, then should be our chief reliance. A long course of Turkish baths may prevent relapse, which is very usual since either exposure to cold or worry induces it.

STUDENTS' COLUMN.

LECTURES ON HUMAN ANATOMY.

By Walter Rivington, M.S., Lond., F.R.C.S., Eng.,
Surgeon to the London Hospital and Lecturer on Anatomy at the London Hospital Medical College.

Lecture IV. *(continued).*

Before entering on the general features and movements and development of the Spine, it will be convenient to complete the description of the Ligaments by describing the mode of union, first of the Sacrum and Coccyx, and then of the Atlas with the Axis and of both with the Skull.
